2. Remove all belts, fan and pulley, crankshaft pulley and pulley hub.
3. Remove oil pan.
4. Unfasten and remove cover, timing pointer and water pump assembly.
5. Reverse removal procedure to install cover, noting data in Figs. 26 and 27.

V8-394

1. Drain cooling system and disconnect radiator lower hose and heater hose from front cover.
2. Disconnect link at generator.
3. Raise front of engine as outlined under *Raising Front of Engine* at the beginning of the engine text.
4. Remove oil pan, fan blades and pulley, and crankshaft pulley.
5. Remove distributor cap and crank engine until distributor rotor points toward front of engine, then remove fuel pump.
6. Unfasten and remove front cover.
7. Reverse removal procedure to install. Always install a new front oil seal. The front cover attaching bolts should be coated with a suitable sealer and tightened to 24-40 ft-lb torque.

TIMING CHAIN

V8-330, 350, 400, 425, 455

1. After removing front cover, remove fuel pump eccentric, oil slinger, crankshaft sprocket, chain and cam-

Fig. 26 Engine front cover bolts. 1964 V8-330

shaft sprocket.

2. Install camshaft sprocket, crankshaft sprocket and timing chain together, aligning timing marks as shown in Fig. 30.
3. Install fuel pump eccentric with flat side rearward, Fig. 31. Then install oil slinger and replace front cover.

V8-394

Place the chain over the sprockets so that when the camshaft sprocket and fuel pump eccentric are bolted to the camshaft hub, the timing marks on both sprockets are facing each other in line with the center of both the camshaft and crankshaft, Fig. 32. The fuel pump eccentric must be assembled with the cupped side out.

Fig. 30 Timing chain position. V8-330, 350, 400, 425, 455

CAMSHAFT, REPLACE

V8-215

1. Remove grille, radiator, front cover, timing chain and sprockets, and intake manifold.
2. Remove rocker arm assembly, push rods and valve lifters.
3. Slide camshaft out of engine.
4. Reverse removal procedure to install camshaft. To provide initial lubrication when installing camshaft, it must first be coated liberally with engine oil.

V8-330, 350, 400, 425, 455

1. Remove grille and radiator.
2. If air conditioned it will be necessary to remove condenser.
3. Remove fuel pump and front cover.
4. Remove oil slinger, timing chain and sprockets.
5. Remove distributor, intake manifold, rocker arm assemblies, push rods and valve lifters.
6. Slide camshaft out of engine.
   NOTE: To insure proper camshaft installation, and to provide initial lubrication, it is extremely important that the camshaft be coated with GM Concentrate (Part No. 582099).

1964 V8-394

1. Drain cooling system and remove oil cooler lines and radiator hoses.
2. If air conditioned, remove condenser.
3. Remove radiator and air cleaner.
4. Remove rocker arm assemblies and push rods.
5. Remove intake manifold, distributor engine top cover and valve lifters.
6. Raise engine and remove oil pan.
7. Remove crankshaft pulley, fuel pump, front cover, fuel pump eccentric, camshaft sprocket and chain.
8. Slide camshaft out of engine.
   NOTE: Before installing camshaft, it is important that it be lubricated liberally with engine oil mixed with GM Concentrate, Part No. 582099.

1963 Olds F.S.C.

1. To remove the camshaft, remove valve lifters.
2. Remove distributor.
3. Remove engine front cover.
4. Remove camshaft thrust plunger, fuel pump eccentric, camshaft sprocket and timing chain.
5. Remove camshaft by carefully sliding it out from front of engine.
6. To install, reverse the above sequence of operations. Lubricate the end of the camshaft thrust plunger with suitable seal lubricant. Set valve timing, ignition timing, adjust carburetor idle and check throttle linkage.

PISTON & ROD, ASSEMBLE

Lubricate the piston pin hole and piston pin to facilitate installation of pin, then position the connecting rod with its respective piston as shown in Figs. 38, 39.

Fig. 27 Engine front cover bolts. V8-330, 350, 400, 425, 455

PISTONS, RINGS & PINS

Senior Cars

Pistons are available in standard sizes and oversizes of .010, .020 and .030".

Rings are available in standard sizes and oversizes of .030" on 1963, and .010 and .030" on 1964-69.

Pins are available in standard sizes and oversizes of .010" on 1963, V8.

F-85 Cars

Pistons are available in standard sizes and oversizes of .010" on 1963, V8, .005, .020 and .030" on 1964-65 V6 and .010 and .030" on 1964-69 V8.

Rings are available in standard sizes and oversizes of .010" on 1963 V8, and .010 and .030" on 1964-69 V8.

Fig. 31 Fuel pump eccentric. V8-330, 350, 400, 425, 455

Fig. 32 Valve timing, V8-394

Pins are available in standard size only.

MAIN & ROD BEARINGS

Senior Cars

Main bearings are available in standard sizes and undersizes of .0005, .001, .0015, .002, .010 and .020″.

Rod bearings are available in standard sizes and undersizes of .002, .010 and .020″. On V8-330 a .012″ undersize is also available.

F-85 Cars

Main bearings are available in standard sizes and undersizes of .001, .002 and .010″ on 1963 V8 and 1964-65 V6. On 1964-68 V8 undersizes of .0005, .001, .0015, .002, .010 and .020″ are available.

Rod bearings are available in standard sizes and undersizes of .001, .002 and .010″ on 1963 V8 and 1964-65 V6. On 1964-68 V8, the undersizes available are .002, .010, .012 and .020″.

NOTE

Main bearing clearances not within specifications must be corrected by the use of selective upper and lower shells. Figs. 41 and 42 illustrate the undersize identification marking on the bearing tang.

IDENTIFICATION (ON SHELL TANG)		THICKNESS
NO. 1 THRU 4	NO. 5	
NONE	NONE	STANDARD
B	A	0005" UNDERSIZE
C	B	.0010" UNDERSIZE
E	C	0015" UNDERSIZE

Fig. 41 Main bearing sizes. V8-394

Fig. 38 Assembly of piston to rod. V8-330, 350, 394, 400, 425, 455

Fig. 39 Assembly of piston to rod. V8-215

OIL PAN

1963 V8-215

1. Remove dipstick and drain oil.
2. Disconnect steering idler arm from relay rod.
3. Remove flywheel housing lower cover.
4. Unfasten and remove pan.

NOTE: On some types of lifts, it may be necessary to drop the oil intake into the pan before the pan can be removed. The crankshaft should be positioned so the counterweights do not interfere with the pan's removal.

1964-65 V6-225

1. Raise car and drain oil.
2. Remove lower flywheel housing.
3. Remove attaching bolts and lower pan enough to remove oil pump pipe and screen-to-cylinder block bolts. *On manual shift transmission jobs it will be necessary to raise engine.*
4. Rotate crankshaft to provide maximum clearance at forward end of pan. Then move front of pan to the right and lower it.

1964 V8-330

Jetstar 88

1. Remove dipstick, hoist car and drain oil.
2. Disconnect pitman arm from steering gear and lower relay rod.
3. Remove starter, flywheel cover and exhaust cross-over pipe.
4. Unfasten and remove oil pan.

F-85 Models

1. Remove dipstick, hoist car and drain oil.
2. Disconnect exhaust pipe from right exhaust manifold.
3. Disconnect front engine mounts and jack front of engine up as far as possible, using a wood block under front of crankshaft hub and wood blocks between halves of front engine mounts.

CAUTION: Be sure distributor does not contact cowl, and fan blades do not contact fan ring.

4. Position No. 1 crankshaft throw up.
5. Remove exhaust cross-over pipe.
6. Remove starter.
7. Unfasten and remove oil pan.

V8-330, 350, 425, 455

1. Remove oil level dipstick.
2. Raise car and drain oil.
3. On F-85 models, disconnect exhaust pipe from right exhaust manifold.
4. On Olds F.S.C models, lower steering relay rod by disconnecting idler arm or pitman arm.
5. Disconnect engine mounts and raise front of engine as far as possible.

CAUTION: Be sure distributor does not contact cowl and fan blades do not contact fan shroud.

6. Bring No. 1 piston up on top center.
7. Remove crossover pipe and starter.
8. Unfasten and remove oil pan.

V8-400

1. Disconnect battery ground cable.

Fig. 42 Main bearing size location. V6-225, V8-215, 330, 350, 400, 425, 455

Fig. 43 Oil pump disassembled. V8-330, 350, 394, 400, 425, 455

2. Remove upper radiator baffle.
3. Remove drive shaft, transmission crossmember, transmission and flywheel.
4. Disconnect left exhaust pipe and starter.
5. Disconnect right-hand engine mount.

NOTE: It is necessary to raise both the front and rear of engine and tilt it to the left, using the left engine mount as a pivot.

6. Use a suitable support bar and insert a 1″ block between tool and right rear corner of oil pan to obtain additional lift on right side.
7. Raise front of engine.

NOTE: Remove lower two right-hand engine cover bolts to permit the lifting tool to clear water pump outlet. Do not bolt tool to block since engine must rock when being raised. Tool No. BT-6501-3 is available for this operation. Position fork of tool to lift pulley hub.

8. Raise right side of engine about 2½″ and insert a block between upper and lower right-hand mounts.
9. Remove support bar tool from rear of engine.
10. Unfasten and remove pan.

NOTE: Before removing pan, have No. 1 and 2 connecting rod journals at the 4 or 7 o'clock position as viewed from front of engine.

11. Reverse procedure to install.

V8-394

1. Position No. 1 piston on bottom of its stroke. This moves No. 1 and 2 crankshaft counterweights out of the way to aid in the pan's removal.
2. Disconnect battery cable.
3. On cars with single exhaust system, remove exhaust crossover pipe.
4. Disconnect idler arm support from frame.
5. Remove attaching bolts and position starter away from engine.
6. Remove the two engine front mount attaching bolts. Then raise engine as outlined under *Raising Front of Engine* at the beginning of the engine text.
7. Drain oil and remove pan. *Holes are provided in the frame crossmember* for access to the front oil pan bolts.

OIL PUMP REPAIRS

V8-330, 350, 394, 400, 425, 455

1. Remove oil pan and pump baffle. Remove attaching screws and remove pump and drive shaft extension.
2. To service the pump, refer to Fig. 43.
3. To install, insert the drive shaft extension through the opening in the block until the shaft mates into the distributor drive gear. Position pump onto rear main bearing cap and torque the attaching bolts to 24-34 ft-lbs.
4. Install oil pump baffle and pan.

V8-215

Removal

1. To remove pump, disconnect oil pressure switch.
2. Clean all dirt from pump-to-front cover joint; also around oil filter joint.
3. Remove oil filter and six pump cover-to-front cover screws.
4. Remove pump cover carefully as idler gear may fall out. Slide out idler and pump drive gears.

Disassemble & Inspect

1. Disassemble pump as indicated in Fig. 44. Wash all parts and blow out all passages with compressed air.
2. Inspect all parts for scoring. Small imperfections may be cleaned up with crocus cloth. *Do not break edges of valve.*
3. Check cover bore for cracks, nicks or warping.
4. Clearance between pressure relief valve and bore should be .0015-.0035″. Too much clearance can affect oil pressure at idle.

Fig. 44 Oil pump cover. V8-215

5. Check clearance of gears which should be .0015-.0075″.

Assembly

1. Install filter by-pass valve into output passage bore (passage with inside diameter ribs) seating squarely in bottom of passage.
2. Install remaining parts as shown in illustration. Tighten caps to 30-35 ft. lbs.

NOTE: When assembled, fill gear pocket completely with petrolatum and force into every cavity of gear pocket; also between teeth of gears. This step is very important, to assist in instant priming when engine is started, unless pump is packed as directed, it may not prime itself when engine is started.

WATER PUMP, REPLACE

V8-215, 330, 350, 400, 425, 455

1. Drain cooling system and remove heater and lower hoses from pump.
2. Loosen pulley belts and remove fan and pulley. On air conditioned cars, remove clutch fan assembly and pulley.
3. Unfasten and remove pump from front cover.

V8-394

1. Drain cooling system below water pump level.
2. Loosen pulley belts, then remove fan, spacer and pulley from front hub.
3. Remove attaching bolts. *On 1963 models, to remove the lower center attaching bolt, rotate the crankshaft pulley until one of the notches machined in the pulley weight is aligned with the lower center bolt.*
4. Remove water pump.
5. When installing the pump, dip the attaching bolts in a suitable sealer.

FUEL PUMP, REPLACE

1. Remove all gasket material from the pump and block gasket surfaces. Apply sealer to both sides of new gasket.
2. Position gasket on pump flange and hold pump in position against its

mounting surface. Make sure rocker arm is riding on camshaft eccentric.
3. Press pump tight against its mounting. Install retaining screws and tighten them alternately.
4. Connect fuel lines. Then operate engine and check for leaks.

SERVICE NOTE: Before installing the pump, it is good practice to crank the engine so that the nose of the camshaft eccentric is out of the way of the fuel pump rocker arm when the pump is installed. In this way there will be the least amount of tension on the rocker arm, thereby easing the installation of the pump.

Clutch and Transmission Section

NOTE: 1969 linkage adjustment information is in this section. Repair procedures on both automatic and manual shift transmissions are covered elsewhere in this manual. Procedures for removing automatic transmissions as well as linkage adjustments on 1963-68 models are included in the automatic transmission chapters. See Chapter Index.

CLUTCH PEDAL, ADJUST

1966-69 All & 1965 Olds F.S.C. (Except Jetstar 88)

1. To adjust clutch pedal free travel, loosen lock nut on adjusting rod and remove swivel retainer.
2. Adjust swivel to obtain a free pedal play of ¾" to 1".
3. Install swivel retainer, tighten lock nut and recheck adjustment.

1963-64 Olds F.S.C. (Except Jetstar 88)

1. Turn back floor mat and adjust clutch pedal bumper until top of pedal pad is 7 15/16" from floor pan. This height must be obtained with clearance between clutch release bellcrank and its stop.
2. Remove clevis pin from clevis at upper end of rod.
3. Move spherical nut on release rod forward until clutch release yoke is free.
4. With pedal bellcrank in raised position, adjust clevis at vertical rod until holes in clevis line up with hole in bellcrank.
5. Lengthen vertical rod by turning clevis about 3 turns, then install rod into bellcrank.
6. Check clearance between clutch release bellcrank and stop. Clearance should be 1/32".
7. Rotate spherical nut until 1 to 1¼" free pedal travel is obtained.

1963 F-85

1. Disconnect lower clutch control rod from equalizer.
2. Adjust rod in or out of trunnion to obtain ⅞" to 1" free travel of clutch pedal.
3. Check free travel of clutch pedal with the lower clutch control rod connected to release yoke.

CLUTCH, REPLACE

All 1966-69 & 1964-65 F-85 & Jetstar 88

1. Remove transmission.
2. Disconnect clutch release spring and clutch rod.
3. Remove clutch release bearing.
4. Remove flywheel housing, leaving starter attached to engine. Release yoke and ball stud will remain in housing.
5. Scribe mark on clutch cover to flywheel for correct assembly.
6. Unfasten and remove clutch cover and disc.
7. Reverse removal procedure to install clutch and adjust clutch pedal free play.

1963 F-85

1. Remove transmission.
2. Remove lower flywheel housing and release bearing.
3. Mark flywheel and clutch cover for correct reassembly.
4. Unfasten and remove clutch cover and disc.
5. Reverse removal procedure to install clutch and adjust clutch pedal free play.

1963-65 Olds F.S.C.

1. Remove transmission as outlined further on. Then remove transmission bearing retainer sleeve.
2. Remove left engine filler plate, engine breather pipe, and right and left rear lower flywheel housing bolts.
3. Remove clutch pedal return spring and disconnect adjustable rod at the yoke.
4. Install engine support bar if one is available. If not, support rear of engine with a suitable jack.
5. Remove engine rear mount bolts at clutch housing and remove frame crossmember by removing three bolts at each end.
6. Remove bolts securing clutch housing to flywheel housing, and remove clutch housing and release yoke.
7. Mark flywheel and clutch cover for correct positioning at reassembly.
8. Remove clutch from flywheel.
9. To install, reverse sequence of removal operations. Use an old transmission mainshaft to align clutch disc while tightening clutch to flywheel. Lubricate clutch shaft pilot bearing and bearing surface of release levers. Adjust transmission shaft linkage and adjust clutch pedal free travel. Lubricate clutch release bearing.

THREE SPEED MANUAL TRANS., REPLACE

1966-69

1. Disconnect throttle linkage from cowl bracket to prevent damage.
2. Raise car and remove drive shaft.
3. Disconnect shift rods from shift levers.
4. Support rear of engine.
5. Remove cross support bar-to-rear transmission mount attaching bolts.
6. Disconnect parking brake cables from cross support and remove cross support bar.
7. If equipped with dual exhaust it may be necessary to disconnect left-hand exhaust pipe at exhaust manifold to provide clearance.
8. Disconnect speedometer cable.
9. Remove transmission upper attaching bolts and install aligning studs in the bolt holes.
10. Remove lower bolts and remove transmission.
11. Reverse procedure to install.

1965 F-85 & Jetstar 88

1. Remove propeller shaft.
2. On column shift models, disconnect shift rods from shift levers at transmission. On floor shift jobs, remove shift lever knob and disconnect back-up lamp wiring (if equipped).
3. Support engine at rear.
4. Remove crossmember attaching bolts.
5. Disconnect parking brake cables from crossmember and remove crossmember.

NOTE: If equipped with dual exhaust, it may be necessary to disconnect left-hand exhaust pipe at manifold to provide clearance.

6. Disconnect speedometer cable (F-85).
7. Unfasten engine from transmission (4 bolts) and slide transmission out of car.

1965 Olds F.S.C.

1. Remove propeller shaft.
2. Disconnect shift rods from shift levers at transmission.
3. Disconnect equalizer shaft at side of transmission.
4. Support engine at rear.
5. Disconnect parking brake cable.
6. Remove crossmember.

NOTE: It may be necessary to disconnect left-hand exhaust pipe from manifold to provide clearance if equipped with dual exhaust.

7. Remove transmission upper attaching bolts and install aligning studs to prevent distortion of clutch disc hub when removing transmission.
8. Remove lower attaching bolts and slide transmission out of vehicle.

1964 F-85 & Jetstar 88

1. Remove propeller shaft and disconnect shift rods from shift levers at transmission.
2. If equipped with floor shift, disconnect shift lever bracket from extension housing and remove shift levers-to-shift shafts, leaving linkage connected to levers. Bracket assembly, levers and linkage can be left hanging in car.
3. Support rear of engine. Remove cross support bar-to-rear transmission mount attaching bolts.
4. Remove cross support bar-to-frame attaching brackets and remove cross support bar.

NOTE: If equipped with dual exhaust, it may be necessary to disconnect left hand exhaust pipe at exhaust manifold to provide clearance.

5. Disconnect speedometer cable.
6. Remove four transmission attaching bolts and slide transmission rearward and out of car.
7. Reverse removal procedure to install the unit.

1963 F-85

1. Disconnect shift rods from transmission levers.
2. Disconnect speedometer cable.
3. Disconnect propeller shaft from transmission companion flange. *Do not let front section of propeller shaft fall loose; move it to one side and tie it to exhaust pipe to avoid damage to center joint ball and seat.*
4. Support rear of engine with high floor stand.
5. Remove rear transmission mount and support bar.
6. Remove four transmission-to-clutch housing bolts.
7. Slide transmission straight back until main drive gear is free of splines in clutch disc.
8. Install transmission in reverse order of removal and adjust shift linkage.

1963-64 Olds F.S.C.

1. Drain transmission and disconnect control rods from transmission.
2. Disconnect speedometer cable at transmission (cable drives off front wheel).
3. Remove propeller shaft.
4. Remove transmission-to-clutch housing bolts and slide transmission rearward until main drive gear clears clutch housing. Lower transmission out of car.
5. Reverse above procedure to install transmission. Apply Lubriplate to the main drive gear shaft. Align propeller shaft, and adjust transmission linkage.

3 SPEED SHIFT LINKAGE, ADJUST

1966-69

On 1969 models, detent must be adjusted as follows. Place transmission in Reverse, loosen shift rods at transmission. Push up on reverse rod until detent in column is felt and tighten bolt for 1st-Reverse rod to 20 ft. lbs. Continue adjustment as follows:

1. Place transmission in Neutral.
2. On 1966-68, loosen swivel nuts on shift rods at transmission.
3. Use a suitable rod as an aligning tool and position it in the slot provided in mast jacket so alignment rod enters holes in low-reverse lever and the interlock pawl.
4. With transmission levers in neutral, tighten swivel nuts to 23 ft-lbs.
5. Remove aligning rod. Make sure neutral positions between low-reverse and second-third are exactly in line. If not, readjust one rod to bring them in line.
6. Check shift operation with engine stopped. Start engine and recheck.
7. On 1969 models, place transmission in Reverse and ignition in "Lock" position. Check to be sure key can be removed, steering wheel will not turn and transmission will not shift out of Reverse.

1965 F-85 & Jetstar 88

1. Loosen swivels and move both transmission shift levers until transmission is in neutral. Neutral detents in transmission cover must both be engaged to make this adjustment correctly.
2. Move selector lever to neutral.
3. Align low-reverse shift lever with 2-3 shift lever.
4. With levers properly aligned in neutral and shift rods free to slide in swivels, center movement of rods in swivels and tighten swivels.
5. Move selector lever through all positions to check adjustment and to insure over-travel in all positions.

1965 Olds F.S.C.

1. Position transmission in neutral.
2. Loosen swivel nuts on shift rods at transmission, being sure rods are free to move in swivels.
3. Slip a suitable aligning pin in slot provided in mast jacket so aligning pin enters holes in low-reverse lever and interlock pawl.
4. With transmission levers in neutral, tighten swivel nuts to 26 ft-lbs.
5. Remove aligning pin and make sure neutral positions between low-reverse and 2-3 levers are exactly in line. If not, readjust one rod to bring them in line.
6. Check shift pattern with engine off. Then start engine and check adjustment.

1964 F-85 & Jetstar 88

1. Move both transmission levers until transmission is in neutral. *Neutral detents in transmission cover must both be engaged. To check, start engine with clutch disengaged and release clutch slowly.*
2. Move selector lever to neutral.
3. Align low-reverse shift lever with the 2-3 shift lever.
4. Install control rods on shift levers.
5. Adjust both shift control rods so as to have a "free pin" fit where rods enter shift levers. Be sure all levers remain aligned in neutral.
6. Move selector lever through all positions to check adjustment and to insure over-travel in all positions.

1963 F-85

1. Loosen trunnion nuts at bottom of steering column-to-equalizer and shift lever rods.
2. Place hand selector lever and shift levers on transmission in neutral.
3. Position shift levers in steering column in alignment with each other as well as horizontal, and tighten trunnion nuts.

1963-64 Olds F.S.C.

1. Set transmission outer shift lever in 2nd gear position.
2. Disconnect shift rod from steering column lower shift lever at clevis.
3. Hold steering column lower shift lever upward against its stop in steering column.
4. Install clevis pin through lower shift lever from bottom side, then adjust clevis so it slides over pin freely. Then shorten shift rod by turning clevis 5½ turns.
5. Install clevis pin and tighten clevis lock nut.

1966-69 3 SPEED HEAVY DUTY TRANS., REPLACE

1. Disconnect throttle linkage from cowl bracket to prevent damage.
2. Raise car and remove drive shaft.
3. Disconnect shift rods from shift levers (column shift).
4. With floor shift, remove shift lever knob and disconnect back-up lamp wiring (if equipped).
5. Disconnect equalizer shaft at side of transmission.
6. Support rear of engine.
7. Disconnect parking brake cable.
8. Remove cross support bar.
9. It may be necessary to disconnect

Fig. 1 Gearshift linkage gauge block can be made locally to the dimensions indicated

Fig. 2 Four speed manual shift transmission linkage adjustment

left exhaust pipe from exhaust manifold to provide clearance if equipped with dual exhaust.

10. Remove transmission upper bolts and install aligning studs in the bolt holes.
11. Remove lower bolts and slide transmission out of car.
12. Reverse procedure to install.

Shift Linkage, Adjust

On 1969 models, detent must be adjusted as follows: Place transmission in Reverse and loosen swivel bolt on back drive rod at equalizer. Push up lightly on back drive rod until stop is felt and tighten bolt to 20 ft. lbs. Continue adjustment.

1. Position transmission in neutral.
2. Loosen clamp screws on shift rods.
3. Use a suitable aligning rod and position it in slot provided in mast jacket so that it enters holes in low-reverse lever and the interlock pawl.
4. With floor shift, a ¼" diameter pin is inserted through shift lever bracket and levers.
5. With transmission levers in neutral, tighten clamp screws to 23 ft-lbs. On 1969 models, place transmission in Reverse and ignition in "Lock" position. Check to be sure key can be removed, steering wheel will not turn and transmission will not shift out of Reverse.
6. Remove alignment rod. Make sure neutral positions between low-reverse and second-third are exactly in line. If not, readjust one rod to bring them in line.

4 SPEED TRANS., REPLACE

1965-69

1. Remove propeller shaft and disconnect shift rods from shift levers at transmission.
2. Disconnect back-up lamp switch wires (if equipped).
3. Support engine at rear.

NOTE: On models with dual exhaust it may be necessary to disconnect left-hand exhaust pipe from manifold to provide clearance.

4. On F-85 models, disconnect speedometer cable.
5. Disconnect parking brake cables from crossmember, then remove crossmember.
6. Remove three bolts that retain shift lever assembly to extension housing. If shift lever assembly removal is not required, it may be left hanging in floor seal.
7. Unfasten transmission and remove from car.

1963 F-85

1. Disconnect speedometer cable and shifter control rods from levers at transmission.
2. Remove propeller shaft.
3. Support rear of engine and remove transmission rear mount and support bar.
4. Remove two upper transmission to clutch housing mounting screws and install guide pins in these holes. Then remove lower screws and slide transmission back and out of vehicle.
5. Install transmission in reverse order and check shift linkage.

4 SPEED SHIFT LINKAGE, ADJUST

1965-69

1. On 1969, place transmission in Reverse and loosen swivel bolt on back drive rod at equalizer. Push up lightly on back drive rod until stop is felt and tighten bolt to 20 ft. lbs.
2. All models: Place transmission in Neutral and loosen shift rods.
3. Using a suitable rod, align levers in Neutral.
4. Adjust swivels to obtain a "free pin" fit at levers. Tighten swivel bolts to 20 ft. lbs.
5. On 1969 models, place transmission in Reverse and ignition in "Lock" position. Check to be sure key can be removed, steering wheel will not turn and transmission will not shift out of Reverse.

1964 F-85 & Jetstar 88

1. Set transmission in neutral position.
2. Move shift lever stud to neutral detent position and insert a $\frac{5}{16}$" locating pin into control lever bracket.
3. Connect 1-2 rod to its lever. Maintaining lever against gauge pin, adjust clevis until its pin freely passes through holes in clevis and lever. Tighten jam nut against clevis.
4. Adjust reverse rod and 3-4 rod in like manner.
5. Remove gauge pin and check shifts for proper operation.

1963 F-85

1. Place transmission in neutral and install gauge, Fig. 1, indicated in position shown in Fig. 2.
2. Remove clevis pin at each lever.
3. On each shift rod, adjust threaded clevis to permit free entry of clevis pin into hole in transmission shift lever.
4. Connect clevises to shift lever.
5. Remove gauge block and check shifts.

NOTE: If any roughness exists, one of the clevises may require adjustment of about ½ turn. Determine the rod and clevis requiring adjustment by sighting along the slot where the gauge block was used.

1969 AUTO. TRANS. LINKAGE, ADJUST

Adjustment procedures for the 1969 models are essentially the same as those for the 1968 units as outlined in the front of this manual.

Rear Axle, Propeller Shaft & Brakes

NOTE: Material marked F.S.C. means Full Size Car or Senior Models

REAR AXLE

Figs. 1, 2 and 3 illustrate the rear axle assemblies used on conventional models. When necessary to overhaul any of these units, refer to the *Rear Axle Specifications* table in this chapter.

Removable Carrier, 1963-64

In these rear axles, Fig. 1 the drive pinion is mounted in two tapered roller bearings that are preloaded by a collapsible spacer. The pinion is positioned by a shim located between the head of the pinion and the rear pinion bearing.

The differential is supported in the carrier by two tapered roller side bearings. These bearings are preloaded by two threaded sleeves or ring nuts between the bearings and pedestals. The differential assembly is positioned for proper ring gear and pinion backlash by varying the adjustment of these ring nuts. The differential case houses two side gears in mesh with two pinions mounted on a pinion shaft which is held in place by a lock screw. The side gears and pinions are backed by thrust washers.

Differential Carrier, Replace

In servicing these rear axles, it is not necessary to remove the rear axle assembly for any normal repairs. The axle shafts and carrier assembly can easily be removed from the vehicle, leaving the axle housing in place.

1. Remove axle shafts and drive shaft as explained below.
2. Drain oil from carrier by removing nuts from carrier studs.
3. Remove carrier assembly from housing.

Fig. 1 Removable carrier type rear axle assembly. 1963-64

Integral Carrier 1963-67 & 1968-69 F.S.C.

As shown in Fig. 2, the drive pinion is mounted on two tapered roller bearings that are preloaded by two selected spacers. The drive pinion is positioned by shims located between a shoulder on the pinion and the rear bearing. The front bearing is held in place by a large nut.

The differential is supported in the carrier by two tapered roller side bearings. These are preloaded by inserting shims between the bearings and the pedestals. The differential assembly is positioned for ring gear and pinion backlash by varying these shims.

Major service work on the differential carrier assembly may be performed with the unit in the car provided a drive-on or twin-post hoist is available. If neither of these hoists are available, the rear axle assembly should be removed from the vehicle. The reason for this is that the axle tubes are pressed into the differential carrier housing and welded.

1968-69 Series 31 to 44

In these rear axles, Fig. 3, the rear axle housing and differential carrier are cast into an integral assembly. The drive pinion assembly is mounted in two opposed tapered roller bearings. The pinion bearings are preloaded by a spacer behind the front bearing. The pinion is positioned by a washer between the head of the pinion and the rear bearing.

The differential is supported in the carrier by two tapered roller side bearings. These bearings are preloaded by spacers located between the bearings and carrier housing. The differential assembly is positioned for proper ring gear and pinion backlash by varying these spacers. The differential case houses two side gears in mesh with two pinions mounted on a pinion shaft which is held in place by a lock pin. The side gears and pinions are backed by thrust washers.

Remove & Replace

Construction of the axle assembly is such that service operations may be performed with the housing installed in the vehicle or with the housing removed and installed in a holding fixture. The following procedure is necessary only when the housing requires replacement.

1. Hoist car and remove rear wheels, drums and axle shafts.
2. Disconnect brake line from wheel cylinders.
3. Unfasten and support backing plates with wire hooks to frame kickup.
4. Disconnect shocks at housing.
5. Position jack stands under frame rear torque boxes, then lower axle housing to stands.
6. Remove springs.
7. Remove propeller shaft and support front of axle housing at companion flange to prevent assembly from rotating when the control arms are disconnected.
8. Remove control arm bolts at axle housing.
9. Remove support at companion flange and lower axle housing.

Fig. 2 Integral carrier type rear axle. 1963-67 and 1968-69 Type "O" axle

10. Remove assembly to bench and transfer parts to new axle housing.
11. Reverse procedure to install.

AXLE SHAFT, REPLACE

1968-69, Series 31 to 44 Type "C"

1. Raise vehicle and remove wheel and brake drum.
2. Clean all dirt from area of carrier cover.
3. Drain lubricant from carrier by removing cover.
4. Remove differential pinion shaft lock screw and shaft.
5. Push flanged end of axle shaft toward center of vehicle and remove "C" lock from button end of shaft.
6. Remove axle shaft from housing, being careful not to damage oil seal.
7. Reverse procedure to install.

1963-64 F.S.C. Except Jetstar 88

Removal

1. Remove wheel. Wheel nuts on left side of car have left-hand threads.
2. Remove the two Tinnerman nuts from wheel studs that hold brake drum in place and remove drum. *If Tinnerman nuts are removed by turning off threads they can be reused. However, if nuts are damaged in any way they must be replaced.*
3. Remove brake backing plate from axle housing (4 bolts).
4. Pull axle shaft bearing retainer plate away from backing plate, taking care not to dislodge backing plate as brake line may be damaged.
5. Pull axle shaft out with a slide hammer-type puller if bearing is a tight fit in axle housing. *While pulling shaft out through seal, support shaft carefully in center of seal to avoid cutting seal lip.*
6. Replace one brake backing plate nut to hold plate in position.

Bearing, Replace

The sealed axle shaft bearings are built with .012 to .015" end play between balls and races and should not be rejected unless end play is greater than .020" or definite roughness between ball and race can be felt when bearing is rotated by hand. The bearing should be checked for roughness and end play before it is removed from the axle shaft because once removed the bearing cannot be used again. *Tipping of either race can cause a large error in end play reading.*

1. With axle shaft removed, remove bearing retainer collar after splitting with cold chisel, Fig. 4.
2. Press bearing from shaft.
3. Press bearing on shaft until it seats against axle shaft shoulder.
4. Press new bearing retainer collar on shaft until it is firmly against bearing.

Installation

Before installing shaft, examine oil seal. Seal has feather edge which forms a tight seal around shaft. If feather edges are damaged in any way, pull seal from housing and install a new one.

1. Remove temporary nut holding brake backing plate to axle housing.
2. Place new gasket over backing plate studs.
3. Slide axle shaft assembly into place, using extreme care not to damage oil seal. *When installing axle shaft on cars with non-slip differential, it will be necessary to align differential side gear and side gear ring splines by inserting axle shaft into side gear ring and rotating shaft slightly to pick up splines in side gear. Do not attempt to force shaft.*
4. Place retainer plate over backing

Fig. 3 Integral carrier type differential. 1968-69 Type "C" axle

Fig. 4 Removing axle shaft bearing retainer

Fig. 5 Propeller shaft installation. 1964-69

Fig. 7 Center bearing bracket. 1963 F-85

Fig. 6 Propeller shaft assembly. 1963 F-85

plate studs and install nuts, tightening them to 55 to 60 ft. lbs.

5. Replace drum and wheel assembly.

All 1965-67, 1968-69 Series 31 to 86, 1963-64 F-85 & Jetstar 88 Type "O"

Removal

1. Remove wheel and brake drum.
2. Remove axle bearing retainer (4 nuts).
3. Pull axle shaft from housing. If bearing is a tight fit in housing, use a slide hammer-type puller, Fig. 3. Do not drag shaft over seal as this may damage seal.
4. Attach one axle bearing retainer nut to hold brake backing plate in position.
5. Before installing axle shaft, examine oil seal. The seals have feathered edges which form a tight seal around the shaft. If these edges are damaged in any way, seal must be replaced. Examine seal surface on shaft; if it is not smooth, dress it down with very fine emery cloth.
6. Reverse removal procedure to install axle shaft, being sure to grease outside of axle bearing, seal surface on axle shaft and bore of axle housing with differential lubricant. Place new gasket and bearing retainer over studs, install nuts and tighten them 45 to 60 ft. lbs.

Installation

Bearings should be replaced if found to be rough or have greater than .020" end play. Remove bearing only when new bearing is to be installed; once removed it must not be reused.

1. With axle shaft removed from housing, split bearing retainer with a chisel, Fig. 4.
2. Press bearing off shaft.
3. Press new bearing on shaft up against shoulder on shaft.
4. Press retainer on shaft up against bearing.
5. Reverse removal procedure to install axle shaft.

PROPELLER SHAFT

1964-69

The rear yoke of the Jetaway equipped cars is bonded in rubber to the inside of the propeller shaft tube and cannot be removed for service. The shaft for the manual shift transmission models is one piece, Fig. 5.

1. To remove, remove nuts holding U-bolts at differential companion flange.
2. If U-joint bearings are not retained by a metal retaining strap, use a piece of wire or tape to hold bear-

Fig. 8 Differential nose angle alignment. 1963 F-85

ings on U-joint cross.

3. Lower rear of shaft and slide rearward.
4. Reverse removal procedure to install the shaft. First, however, apply one ounce of seal lubricant to the splines of the slip yoke on Jetaway and Jetstar 88.

1963 F-85

1. Referring to Fig. 6, remove U-bolts from companion flanges at transmission and differential.
2. If U-joint bearings that attach to companion flange are not retained with a metal retainer, use a piece of wire or tape to hold bearings on their spider or cross before removing from flange.
3. Remove two bearing support-to-body bolts and remove shaft assembly. *When handling the drive shaft assembly, extreme care must be taken not to allow one shaft to "flop" around loosely as this may damage the center ball seat.*
4. To install, position center bearing support on bearing insulator and attach to body. Torque bolts 10 to 18 ft. lbs., Fig. 7.
5. Attach U-bolts to companion flanges and torque U-bolt nuts 14 to 18 ft. lbs. Tighten each side uniformly before final torque is applied. Bend lock tangs over nuts. *Inspect center bearing rubber insulator to be sure that edges of insulator did not become folded under while installing it in support bracket.*

Center Bearing & Mount

1. With shaft removed, slide bearing-to-body mounting forward off bearing.
2. Pry crimped area of slip yoke nut retainer away from nut; then unscrew nut until it is free of threads.
3. Pull rear shaft from front shaft. *Watch for index wire in one spline of slip yoke. It is important that this wire be kept in same spline.*
4. Remove nut retainer and rear spacer.
5. Remove slip yoke seal at this time if necessary to replace it.
6. Use puller to remove center bearing. Bearing and insulator are serviced as an assembly. The groove between bearing and front of bearing retainer must be packed with waterproof grease.

Assemble

1. Drive new bearing on shaft until it is seated.
2. Place rear spacer, then nut retainer on front propeller shaft with tang of retainer indexing slot of propeller shaft. Cupped side of nut retainer must face rearward.
3. Apply special spline lubricant to front propeller shaft splines.
4. Install new slip yoke seal at this time if old seal was removed.
5. Align slip yoke index spring wire with wide serration in front propeller shaft; then insert slip yoke into front shaft.
6. Torque slip yoke nut 50 to 75 ft. lbs. Crimp nut retainer against nut in two places.

Propeller Shaft Alignment

If drive line shudder, roughness or vibration is experienced, it may be due to incorrect propeller shaft alignment or differential nose angle. To make this check, a special tool consisting mainly of a cable, Fig. 8, is used.

1. Install tool at front arm of front cross bar as shown. The line to engine spacer is installed after rear bracket has been attached to differential.
2. Place indicator against pinion companion flange and cable must be in notch marked "F85".
3. If necessary to adjust, remove shim from front of lower suspension arm if cable is below notch. If cable is above notch, add shims. *The same amount of shims must be added to both sides. A 1/8" shim will raise or lower nose angle approximately 1/16".*

BRAKE ADJUSTMENTS

All 1963-69 & 1963 F-85

These brakes, Fig. 15, have self-adjusting shoe mechanisms that assure correct lining-to-drum clearances at all times. The automatic adjusters operate only when the brakes are applied as the car is moving rearward or when the car comes to an uphill stop.

Although the brakes are self-adjusting, an initial adjustment is necessary after the brake shoes have been relined or replaced, or when the length of the star wheel adjuster has been changed during some other service operation.

Frequent usage of an automatic transmission forward range to halt reverse vehicle motion may prevent the automatic adjusters from functioning, thereby inducing low pedal heights. Should low pedal heights be encountered, it is recommended that numerous forward and reverse stops be made until satisfactory pedal height is obtained.

NOTE

If a low pedal height condition cannot be corrected by making numerous reverse stops (provided the hydraulic system is free of air) it indicates that the self-adjusting mechanism is not functioning. Therefore, it will be necessary to remove the brake drum, clean, free up and lubricate the adjusting mechanism. Then adjust the brakes as follows, being sure the parking brake is fully released.

Adjustment

NOTE: Inasmuch as there is no way to adjust these brakes with the drums installed, the following procedure is mandatory after new linings are installed or if it becomes necessary to change the length of the brake shoe adjusting screw.

1. With brake drums removed, position the caliper shown in Fig. 16 to the inside diameter of the drum and tighten the clamp screw.
2. Next position brake shoe end of the caliper tool over the brake shoes as shown in Fig. 17.
3. Rotate the gauge slightly around the shoes to insure that the gauge contacts the linings at the largest diameter.
4. Adjust brake shoes until the gauge is a snug fit on the linings at the

Fig. 15 Right rear and front brake. All 1963-69 and 1963 F-85

Fig. 16 Brake shoe gauge measuring inside diameter of brake drum. 1963-69

point of largest lining diameter.

NOTE: If it is necessary to back off the brake shoe adjustment, it will be necessary to hold the adjuster lever away from the adjuster screw, Fig. 18.

PARKING BRAKE, ADJUST

1963-69

With parking brake fully released, adjust rear cables by first tightening the brake equalizer adjusting nut until a heavy resistance is felt when rotating rear wheels forward. Then loosen equalizer adjusting nut 7 full turns (10 on 1963).

Fig. 17 Brake shoe gauge measuring outside diameter of brake shoes. 1963-69

POWER BRAKE UNIT, REPLACE

1967-69

1. Disconnect vacuum hose from vacuum cylinder and cover openings to prevent entrance of dirt.
2. Disconnect pipes from master cylinder outlets and cover openings in master cylinder and end of pipes to prevent entrance of dirt.
3. Loosen inboard master cylinder attaching nut to disengage metering valve (disc brakes only).
4. Disconnect air valve rod from brake pedal.
5. Unfasten and remove power brake unit.
6. Reverse procedure to install.

1964-66

1. Disconnect hydraulic line. Plug or tape line to prevent dirt from entering hydraulic system.
2. Disconnect vacuum line from vacuum check valve.
3. Disconnect operating rod from brake pedal.
4. Unfasten (4 nuts) and remove power unit from cowl.
5. Reverse removal sequence to install and torque attaching nuts to 20-27 ft-lbs.

1963

1. Disconnect hydraulic line. Plug or tape line to prevent dirt from entering hydraulic system.
2. Disconnect vacuum lines from vacuum cylinder.
3. Disconnect operating rod from brake pedal.
4. Unfasten vacuum cylinder from cowl (4 nuts).
5. Reverse sequence of operations to install and torque attaching nuts 8-16 ft. lbs.

BRAKE MASTER CYLINDER, REPLACE

1964-69

The standard brake master cylinder on Olds F.S.C. can be removed without disconnecting the push rod and clevis. On all cars equipped with power brakes, the master cylinder can be removed without removing the vacuum cylinder from the car.

1. Be sure area around master cylinder is clean, then disconnect the hydraulic lines at master cylinder. Plug or tape end of line to prevent entrance of dirt or loss of brake fluid.
2. On F-85 models, remove push rod-to-brake pedal clevis pin.
3. On all models, unfasten (4 bolts) and remove master cylinder.

1963 F-85

Be sure area around master cylinder is clean, then disconnect hydraulic line at master cylinder. Plug or tape end of line to prevent entrance of dirt.

Remove four attaching nuts and remove master cylinder. It is not necessary

Fig. 18 Backing off brake shoe adjustment

to disconnect the push rod and clevis.

Install master cylinder, fill reservoir with fluid and bleed system.

1963 F.S.C.

The standard brake master cylinder can be removed without disconnecting the push rod and clevis. The master cylinder on cars with power brakes can be removed without removing the vacuum cylinder from the car. Power cylinders can be identified by the bronze Moraine cylinder and the black Bendix cylinder.

1. Disconnect hydraulic line at master cylinder and plug or tape end to prevent dirt entering the system.
2. If equipped with standard transmission, install a gauge pin in the holes provided in the frame side rail and "X" member to hold clutch linkage in position; then disconnect clutch linkage from clutch pedal bellcrank and remove bellcrank.
3. Remove master cylinder (4 nuts). On Moraine units, remove and record number of any shims found between master and power cylinders. *On Moraine units, the master cylinder piston will remain attached to the vacuum unit. If piston is to be serviced, the vacuum unit must be removed and disassembled.*

Front End and Steering Section

NOTE: Material marked Olds F.S.C. means Full Size Car or Senior Models

FRONT SUSPENSION

As shown in Figs. 1, 2 and 3, the front suspension is of the conventional "A" frame design with ball joints. Double acting shock absorbers are mounted within the coil springs. Caster and camber are controlled by shims.

LUBRICATION

An extended lubrication period of every six months or 12,000 miles is prescribed, whichever occurs first. The ball joints, are fitted with plugs which must be removed and grease fittings installed. After applying the approved type of grease, remove the fittings and reinstall the plugs.

IMPORTANT: On Intermediates, if ball joints are noisy, the plugs must be removed and approximately one teaspoonful of specified grease applied directly to the plug hole with a hand-operated, ball type nozzle grease gun. Do not install grease fittings or attempt to fill with a pressure gun. Either method will result in overfill or mixing of greases which may harm the part.

Before using a new grease gun of this type, first count the number of turns or pumps required to obtain approximately one teaspoonful of grease.

Fig. 1 Front suspension. 1963-64 Olds F.S.C.

WHEEL ALIGNMENT

1963-69 Full Size Cars

Camber and caster are adjusted by shims placed between the upper pivot shafts and the frame. In order to remove or install shims, *do not remove weight from front wheels.* Loosen pivot shaft-to-frame bolts. To gain access to these bolts, loosen top and rear fasteners on fender filler plate aprons.

To decrease positive caster, add shim at the front bolt. To increase positive caster, remove shim at the front bolt.

To increase camber, remove shims at both front and rear bolt. To decrease camber, add shims at both bolts.

By adding or subtracting an equal amount of shims from both front and rear bolts, camber will change without affecting caster adjustment. When changing shims, refer to Figs. 5 and 6.

1963-69 Intermediates

Caster and camber is adjusted by shimming at the upper control arm shaft attaching points. See Figs. 7 and 8.

Adding shims at the front locations will change caster toward negative with practically no change in camber. Adding shims at the rear locations will change caster toward positive and camber toward negative. Adding equal shims at both front and rear locations will not change caster but will change camber toward negative.

To adjust, loosen both front and rear bolts to free shims for removal or addition.

TOE-IN, ADJUST

To adjust the toe-in, loosen the clamps at both ends of the adjustable tubes at each tie rod. Then turn the tubes an equal amount until the toe-in is correct. Turning the tubes in the direction the wheels revolve when the car moves forward decreases the toe-in and vice-versa. When the adjustment is complete, tighten all clamp screws.

The steering knuckle and steering arm "rock" or tilt as front wheel rises and falls. Therefore, it is vitally important to position the bottom face of the tie rod

Fig. 2 Front suspension. 1965-69 Full Size Car

Fig. 3 Front suspension. 1963-69 Intermediate Models

end parallel with the machined surface at the outer end of the steering arm when tie rod length is adjusted. Severe damage and possible failure can result unless this precaution is taken. The tie rod sleeve clamps must be straight down to provide clearance.

WHEEL BEARINGS, ADJUST

1965-69 Full Size Cars (Except Jetstar 88)

1. While rotating hub and drum assembly at least three times the speed of nut rotation, tighten nut to 30 ft-lbs to insure all parts are properly seated.
2. Back off nut ½ turn.
3. Retighten nut finger tight and install retaining ring or cotter key if possible. If unable to install retaining ring or cotter key, back off nut (not to exceed 1/24 of a turn) until tabs on clip align with serrations in nut.

1965-66 F-85 & Jetstar 88

1. While rotating hub and drum assembly at least three times the speed of nut rotation, tighten nut with a torque wrench 25-30 ft-lbs to insure that all parts are properly seated and threads are free.
2. Back off nut ½ turn, then retighten nut finger tight.
3. If unable to install cotter pin (or retainer on Jetstar 88) at finger tight position, back off to first notch and install cotter pin (or retainer).

1964 Olds F.S.C.

1. While rotating hub and drum assembly, at least three times the speed of nut rotation, torque nut to 25-30 ft-lbs.
2. Back off nut ½ turn. Then retighten nut finger tight and install retainer ring or cotter pin if possible. If unable to install retainer, back off nut (not to exceed 1/12 turn) until slot in nut and keyway align, then install retainer or cotter pin.

Shim Thickness	One shim added to or subtracted from BOTH BOLTS will change camber	One shim added to or subtracted from FRONT BOLT ONLY will change caster
.020"	1/8°	5/16°
.050"	5/16°	1/2°
.120"	5/8°	1-3/8°

Fig. 5 Wheel alignment shim data. 1963-64 Olds F.S.C.

1964 F-85

1. Tighten adjusting nut with a torque wrench to 25-30 ft-lbs while revolving wheel at least three times the speed of nut rotation.
2. Back off nut ½ turn. Then retighten nut finger tight.
3. If unable to install cotter pin at finger tight position, back off to first notch and install cotter pin.

1963 F-85

1. Tighten spindle nut 10-15 ft-lbs torque while rotating hub to seat bearings.
2. Back nut off 1/6 turn minimum ¼ maximum to allow installation of cotter pin.

1963 Olds F.S.C.

1. Tighten spindle nut with a torque wrench to 23-25 ft-lbs while rotating wheel to seat bearings.
2. Back off nut ½ turn and then re-

Shim Thickness	One shim added to or subtracted from BOTH BOLTS will change camber	One shim added to or subtracted from FRONT BOLT ONLY will change caster

120"	3/4°	1°

Fig. 8 Wheel alignment shim data. 1964-69 Inter.

tighten nut 15-17 ft-lbs.
3. If keyway in wheel spindle and a slot in nut line up, back off nut one notch; otherwise back off nut to the nearest slot and install retainer.

WHEEL BEARINGS REPLACE

(Disc Brakes) 1967-69

1. Raise car and remove front wheels.
2. Remove brake pads and caliper assembly but do not disconnect brake line. Suspend caliper from a wire loop or hook to avoid strain on the brake hose.
3. Remove grease cap, cotter pin and nut. Pull off hub and disc assembly. Grease retainer and inner bearing can now be removed.

CHECKING BALL JOINTS FOR WEAR

If loose ball joints are suspected, first be sure the front wheel bearings are properly adjusted and that the control arms are tight. Then check ball joints for wear as follows:

Referring to Fig. 9, raise wheel with a jack placed under the lower control arm as shown. Then test by moving the wheel up and down to check axial play, and rocking it at the top and bottom to measure radial play.

1. Upper ball joint should be replaced if there is any noticeable looseness at the joint.
2. Lower ball joint should be replaced if radial play exceeds .250".
3. Lower ball joint should be replaced if axial play between lower control arm and spindle exceeds the following:

1963-64 Olds F.S.C. ..... .125

Fig. 9 Checking ball joints for wear

1963-64 Olds F-85 090
1965-66 All Series ..... .125

BALL JOINTS, REPLACE

Ball joints are mounted in the control arms in three ways. On some models the ball joints are riveted to the control arms. All service ball joints, however, are provided with bolt, nut and washer assemblies for replacement purposes.

Some ball joints are pressed into the control arms, in which case they may be pressed out and new ones installed. However, 1963 Senior models, the upper ball joint is supplied only with the control arm.

SHOCK ABSORBER, REPLACE

Senior Models

1. Remove upper pivot bolt from shock absorber.
2. Remove two capscrews and washers attaching shock absorber to lower control arm and remove shock absorber.
3. Reverse above procedure to install.

Intermediate Models

1. Remove upper attaching nut, retainer and grommet from shock absorber.
2. Remove two bolts and washers attaching shock absorber to lower control arm and remove shock absorber.
3. To install, position grommet and retainer over shock and slide shock up through spring and frame. Install and tighten attaching nut and lower capscrews.

COIL SPRING, REPLACE

Senior Models

1. Raise front of car and support frame with floor stands.
2. Remove wheel and disconnect speedometer cable from steering knuckle (if equipped).
3. Disconnect stabilizer link and speedometer cable clamp from lower control arm.
4. Loosen lower control arm shaft bushing bolts.
5. Remove shock absorber.
6. Position floor jack under lower control arm between spring seat and ball joint. Raise jack until it supports lower control arm.
7. Disconnect lower ball joint from steering knuckle.
8. Slowly lower floor jack until spring is fully extended and remove spring.

IMPORTANT: Left and right coil springs should not be interchanged. Spring part number is stamped on outer side of end coil.

INSTALLATION: Reverse removal procedure to install spring. However, first tape spring insulator to top of spring at least six places. Top of spring may be identified by flat coil which will allow insulator to seat squarely on top coil.

While holding spring and insulator against pilot in frame crossmember, tilt spring so it will pivot in lower control arm, Fig. 10. Rotate spring so end of bottom coil will index with edge of hole in control arm spring seat. Coil should not cover any portion of hole.

Intermediate Models

1. Raise front of car and support frame

Fig. 10 Front spring installation. Senior Models

Fig. 11 Front spring positioning. F-85 models

with floor stands.
2. Remove wheel. Disconnect stabilizer link from lower control arm.
3. Remove shock absorber.
4. Position floor jack between spring seat and ball joint with handle straight out from car to support lower control arm.
5. Disconnect lower control arm from ball joint.
6. Block upper control arm and backing plate up out of the way.
7. Slowly lower floor jack until spring is fully extended and remove spring.

Installation

1. While holding spring against pilot in frame, tilt spring so it will pilot in lower control arm. Rotate spring so end of top coil will index against step in upper spring seat, Fig. 11.
2. Position floor jack with handle straight out from car, between spring seat and ball joint.
3. Lower upper control arm and backing plate into position.
4. Raise lower control arm until ball joint is tight in steering knuckle. Install ball joint nut, torque it to 40 ft-lbs and insert cotter pin. *Use extreme care to prevent spring from dislodging while raising jack.*
5. Complete the installation in reverse order of removal.

MANUAL GEAR, REPLACE

1964-69

1. Remove two flex coupling flange nuts.
2. Hoist and support car with stands under outer ends of lower control arms.
3. Remove nut and use a puller to remove pitman arm.
4. Remove gear-to frame bolts.
5. Position steering linkage and speedometer cable (if equipped) out of the way and withdraw gear assembly from under car.
6. Reverse procedure to install unit.

1963 F-85

To facilitate removal of the steering gear from the car, it will be necessary to raise the steering shaft in the column assembly.

1. Remove steering shaft coupling clamp bolt and slide clamp off coupling housing onto steering gear worm shaft. Mark steering shaft in line with slot at coupling clamp surface.
2. Disconnect horn wire from harness.
3. Pull off steering wheel.
4. Pull horn contact plate out of recess in actuator to give clearance for removal of upper bearing retainer clip. Pry clip out of actuator housing.
5. Pull steering shaft out of steering column and block shaft up about two inches.
6. Remove left-hand end plug from relay rod and pull relay rod off pitman arm.
7. To install, reverse procedure.

POWER STEERING

Service Notes

Before installing the steering gear, apply a sodium soap fine fibre grease to the gear mounting pads to prevent squeaks between the gear housing and frame. Make sure the alignment pin on the gear housing enters the hole provided in the frame side rail.

Make certain there is a minimum of .040″ clearance between coupling hub and steering gear upper seal.

Install coupling flange hub and torque to 20-25 ft-lbs. Before tightening the gear-to-frame bolts, shift the gear as necessary to place it in the same plane as the steering shaft so that the flexible coupling is not distorted. Tighten gear-to-frame bolts to 60-80 ft-lbs. and pitman shaft nut to 120-150 ft-lbs.

Steering Gear, Replace

1963-69 F.S.C. & 1964-69 Intermediates

1. Remove coupling flange hub bolt.
2. Disconnect hoses from pump and cap pump and hose fittings.
3. Remove pitman arm nut and, using a suitable puller, remove pitman arm.
4. Remove gear-to-frame bolts. Permit lower shaft to slide free of coupling flange, then remove gear with hoses attached.

1963 F-85

1. Remove coupling flange nuts, and ground wire from flange attaching bolt.
2. Disconnect hoses from pump and gear. Cap pump, hose fittings and gear connectors.
3. Disconnect horn wire from harness. On all models, pull off wheel. Also pull horn contact out of recess in actuator to give clearance for removal of upper bearing retainer clip. Pry clip out of actuator housing.
4. Pull steering shaft out of steering column and block shaft up about two inches.
5. Disconnect relay rod from pitman arm. Remove four bolts attaching gear to front suspension cross bar and remove coupling from gear.
6. Reverse removal procedure to install, tightening gear attaching nuts to 45-60 ft. lbs.
7. Remove four bolts attaching gear to suspension cross bar and remove gear from car.
8. Reverse removal procedure to install gear. Torque pitman shaft nut to 100-125 ft. lbs. Torque gear attaching bolts to 45-50 ft. lbs.

1963 Olds F.S.C.

1. Remove steering wheel and loosen column upper clamp-to-bracket bolts.
2. Fold back floor mat and remove mast jacket cover plate from toe pan.
3. Hoist front of car and support it with floor stands under outer ends of lower control arm.
4. Remove nut and pull off pitman arm, using a suitable puller.
5. Remove gear-to-frame bolts.
6. Position steering linkage and speedometer cable out of way and remove steering gear from under car.
7. Reverse removal procedure to install the gear. Before tightening gear to frame and upper column clamp bolts, position column to obtain $2\frac{7}{32}$″ between horn contact and end of worm shaft to provide $\frac{1}{8}$″ to $\frac{3}{16}$″ clearance between turn signal housing and steering wheel. Tighten upper mast jacket clamp before tightening frame bolts. Torque frame bolts 60 to 80 ft-lb and pitman shaft nut 90 to 120 ft-lb.

TORONADO SUPPLEMENT

Items covered in this section apply to the Toronado only. For service procedures and specifications not covered here, refer to the conventional Oldsmobile section of this chapter.

Engine & Transmission Section

ENGINE REPLACE

1. Drain radiator and remove hood, marking hinge as a guide for reassembly.
2. Disconnect battery, radiator hoses, cooler lines, heater hoses, vacuum hoses, power steering pump hoses, engine-to-body ground strap, fuel hose from fuel line, wiring and accelerator cable.
3. Remove coil, throttle control switch bracket, radiator support and radiator.
4. Raise car and disconnect exhaust pipes at manifold.
5. Remove starter.
6. Remove torque converter cover and three bolts securing converter to flywheel.
7. Attach a tool of the type shown in Fig. 1 to support final drive assembly.
8. Remove two bolts from right output shaft support bracket and one through bolt attaching final drive to engine block on left side.
9. Remove engine mount-to-crossmember nuts.
10. Lower car and support engine with a fixture of the type shown in Fig. 2.
11. Remove six transmission-to-engine bolts and lift engine from car.

NOTE: If car is to be moved, install a converter holding tool of the type shown in Fig. 1.

Installation

1. Lower engine into position.
2. Locate engine dowels into transmission and position mount studs into front crossmember.
3. Secure engine to transmission (6 bolts).
4. Remove engine lifting rig and raise car.
5. Secure torque converter to flywheel.
6. Install engine mount nuts.
7. Install torque converter cover and starter.
8. Install two bolts attaching right output shaft support bracket and one through bolt attaching final drive to engine block on left side.
9. Remove final drive supporting tool.
10. Connect exhaust pipes and lower car.
11. Install remaining parts removed in reverse order of removal.

ENGINE FRONT COVER

With Engine & Oil Pan Removed

1. Disconnect by-pass hose from water pump.
2. Remove cover-to-block bolts and remove cover, timing pointer and water pump.
3. Install cover and torque as shown in Fig. 2.

Oil Pan

1. Remove engine as outlined.
2. Remove dipstick, drain oil and remove mount from front cover.
3. Unfasten and remove oil pan.
4. Apply sealer to both sides of pan gaskets (cork) and install on block.
5. Install front and rear rubber seals.
6. Wipe lube on seal area and install pan. Torque $\frac{5}{16}$" bolts to 15 ft-lbs and ¼" bolts to 10 ft-lbs.
7. Install mount on front cover and install engine.

TRANSMISSION

Less Final Drive

Removal

1. Disconnect battery, oil cooler lines at transmission and speedometer cable at governor.
2. Install engine support rig of the type shown in Fig. 3.
3. Remove nut "D" and bolts "A", "B" and "C", Fig. 4. A special wrench must be used on nut "D".
4. Remove bolts indicated in Fig. 5.
5. Remove flywheel cover plate bolts.
6. Hoist car and remove starter.

Fig. 1 Final drive supporting tool

Fig. 2 Engine front cover bolts

Fig. 3 Installing support bars

Fig. 4 Transmission attachment

Fig. 5 Transmission-to-engine attachment

Fig. 6 Transmission-to-engine attachment

Fig. 7 Engine mount attachment

Fig. 8 Shift linkage adjustment

7. Rotate flywheel until all bolts are removed.
8. Disconnect vacuum modulator line and stator wiring.
9. Install transmission lift.
10. Remove shift linkage.
11. Remove bolts "E", "F" and "G" and nut "H", Fig. 4.

NOTE: When last three transmission-to-final drive bolts are removed a quantity of oil will be lost.

12. Remove bolts indicated in Fig. 6.
13. Remove bolts indicated in Fig. 7. Then remove the four bracket-to-engine mount bolts.
14. Slide transmission rearward and down. Engine mount bracket will follow transmission down. Install converter holding tool, Fig. 1.
15. After transmission is removed from car, the link assembly cover insulator can be removed or installed.

Installation

When installing the transmission, the motor mount bracket must be positioned loosely on the link assembly cover until the transmission is in place; then reverse removal procedure. Torque bolts to ft-lbs as follows:

Engine-to-converter housing	25
Engine bracket-to-transmission	55
Engine bracket-to-rubber mount	55
Oil cooler lines to transmission	25
Final drive-to-transmission	25
Converter-to-flywheel	30
Flywheel housing cover	5
Starter-to-transmission	30

Adjust shift linkage as directed in Fig. 8.

Drive Axles & Final Drive Section

DRIVE AXLES

Description

Drive axles are a complete flexible assembly and consist of an axle shaft and an inner and outer constant velocity joint, Fig. 1. The right axle shaft has a torsional damper mounted in the center. The inner constant velocity joint has complete flexibility plus inward and outward movement. The outer constant velocity joint has complete flexibility only.

NOTE: Whenever any operations call for disconnecting, connecting, removal or installation of the drive axles, care must be used to prevent damage to constant velocity joint seals. Seals may be wrapped with floor mat rubber or old inner tube, etc. Make sure rubber protective covers that are used are removed before car is started or driven.

DRIVE AXLE REPLACE

Right Side Unit

Removal

1. Hoist car under lower control arms.
2. Remove axle nut, Fig. 3.
3. Push inner C.V. joint outward enough to disengage from R.H. final drive output shaft and move rearward.
4. Remove R.H. output shaft bracket bolts to engine and final drive.
5. Remove R.H. output shaft.
6. Drive axle assembly will be removed now.

NOTE: Care must be used to see that C.V. joints do not turn to full extremes and that seals are not damaged against shock absorber or stabilizer bar.

Installation

1. Place R.H. drive axle into lower control arm and enter outer race splines into knuckle.
2. Lubricate final drive output shaft seal with approved seal grease.
3. Install R.H. output shaft into final drive and attach support bolts to engine and brace. Torque to 50 ft-lbs.
4. Move R.H. drive axle toward front of car and align with R.H. output shaft. Install attaching bolts and torque to 65 ft-lbs.
5. Install oil filter element.
6. Install washer and nut on drive axle. Torque to 60 ft-lbs and insert cotter pin.

Left Side Unit

Removal

1. Hoist car under lower control arms.
2. Remove wheel and drum.
3. Remove drive axle nut.
4. Position access slot in hub so that each attaching bolt (4) can be removed, Fig. 4. It will be necessary to push aside adjuster lever to remove one of the bolts.
5. Remove hub assembly, Fig. 4. It will be necessary to push aside adjuster lever for clearance.
6. Remove tie-rod end nut.
7. Using a hammer and brass drift, drive on knuckle until tie-rod end stud is free.
8. Remove bolts from drive axle and L.H. output shaft, Fig. 5.
9. Remove upper control arm ball joint nut. Using hammer and brass drift, drive on knuckle until upper ball joint stud is free, Fig. 6.
10. Remove ball joint, Fig. 7, being careful not to damage drive axle seal.
11. Remove knuckle and support so that brake hose is not damaged.
12. Carefully guide drive axle out.

NOTE: Care must be used to see that C.V. joints do not turn to full extremes and that seals are not damaged against shock absorber or stabilizer bar.

Fig. 1 Drive axle assembly (left side)

Fig. 2 Drive axle disassembled (right side)

Fig. 3 Drive axle installed

Fig. 4 Removing hub

Fig. 5 Installing support block

Fig. 6 Removing upper ball joint

Installation

1. Guide L.H. drive axle onto lower control arm in position on block, Fig. 5.
2. Insert lower ball joint stud into knuckle and attach nut (do not tighten).
3. Center L.H. drive axle in opening of knuckle and insert upper ball joint stud.
4. Place brake hose clip over upper ball joint stud and install nut (do not tighten).
5. Insert tie-rod end stud into knuckle and attach nut. Torque to 45 ft-lbs and insert cotter pin.
6. Lubricate hub bearing OD with E.P. grease and install. Torque to 65 ft-lbs.
7. Align inner C.V. joint with output shaft and install attaching nuts. Torque to 65 ft-lbs.
8. Torque upper and lower ball joint nuts to 40 ft-lbs and insert cotter pins.

NOTE: Upper ball joint cotter pin must be crimped toward upper control arm to prevent interference with outer C.V. joint seal.

9. Install drive axle washer and nut. Torque to 60 ft-lbs and install cotter pin.
10. Install drum and wheel.
11. Lower car and check wheel alignment.

C.V. JOINT SERVICE

NOTE: The C.V. joints are to be replaced as a unit and are only disassembled for repacking and replacement of seals.

Outer C.V. Joint

Disassemble

1. Insert axle in vise, clamping on mid-portion only.
2. Remove inner and outer seal clamps, Fig. 8.
3. Slide seal down axle shaft to gain access to C.V. joint.
4. Referring to Fig. 9, spread retaining ring until C.V. joint can be removed from axle spline.
5. Remove retaining ring, Fig. 10.
6. Slide seal from axle shaft.
7. Remove grease from C.V. joint.
8. Holding C.V. joint with one hand, tilt cage and inner race so that one ball can be removed. Continue until all six balls are removed, Fig. 11.
9. Turn cage 90° and with large slot in cage aligned with land in inner race, lift out, Fig. 12.
10. Turn inner race 90° in line with large hole in case, lift land on inner race up through large hole in cage and turn up and out to separate parts, Fig. 13.

Inspection

Wash all metal parts in cleaning solvent and dry with compressed air. Rubber seal should be replaced whenever joint is disassembled for service. Inspect all metal parts for nicks, cracks, breaks or scores. If any defects are found the joint assembly will have to be replaced as a unit.

Reassemble

1. Insert land of inner race into large hole in cage and pivot to install in cage, Fig. 13.
2. Align inner race as shown in Fig. 12 and pivot inner race 90° to align in outer race as shown in Fig. 14.
3. Insert balls one at a time until all six are installed. Inner race and cage will have to be tilted as shown in Fig. 14 so that each ball can be inserted.

Fig. 7 Removing lower ball joint

Fig. 8 Cutting seal clip

Fig. 9 Removing retaining ring

4. Pack joint full of approved lubricant. Pack inside of seal with approved lubricant until folds of seal are full.
5. Place small keystone clamp on axle shaft.
6. Install seal on axle shaft.
7. Install retaining ring into inner race, Fig. 10.
8. Insert axle shaft into splines of outer C.V. joint until retaining ring secures shaft.
9. Position seal in slot of outer race.
10. Install large keystone clamp over seal and secure, Fig. 15. Then install small keystone clamp over seal and secure, Fig. 16.

Fig. 10 Removing or installing retaining ring

Fig. 11 Removing balls from outer race

Fig. 12 Positioning cage for removal

Inner C.V. Joint

Disassemble

1. Clamp mid-portion of axle shaft in vise.
2. Remove small seal clamp.
3. Remove large end of seal from C.V. joint by prying out peened spots and driving off C.V. joint with hammer and chisel, Fig. 17.
4. Slide seal down shaft until C.V. joint is disassembled. Remove O-ring from outer housing, Fig. 18.
5. Wipe all excess grease from C.V. joint.
6. Remove axle shaft retaining ring, Fig. 18.
7. Remove retaining ring from interior of ball spline outer housing, Fig. 18.
8. Remove ball spline outer housing from ball spline inner housing, being careful not to drop or lose balls (five in a line with six rows).
9. Follow disassembly of outer C.V. joint from Steps 4 thru 9 for inner C.V. joint.
10. Remove grease from inside of ball spline outer housing.
11. Using wood block, carefully drive along outer edges from inside of ball spline outer housing and remove retaining cup.
12. Remove O-ring from interior of ball spline outer housing, Fig. 19.
13. Remove retaining ring from interior of ball spline outer housing.
14. Remove O-ring from exterior of ball spline outer housing.
15. Remove two retaining rings from ball spline inner housing, Fig. 20.

Inspection

Wash all metal parts in cleaning solvent and blow dry with compressed air. Inspect all parts for damage. If any defects are found, replace C.V. joint as a unit.

Reassemble

1. Install two retaining rings on inner spline housing, Fig. 20.
2. Install retaining ring in groove of outer spline housing, Fig. 19.
3. Install O-ring into inner groove of outer spline housing. Lubricate O-ring with approved seal lube.
4. Install cover into outer spline housing, Fig. 21. Care must be used not to damage O-ring.
5. Insert land of inner race into large hole in case and pivot to install in cage, Fig. 22.
6. Align inner race and cage and install into inner spline housing, Fig. 20.
7. Insert balls in inner spline housing one at a time until all six balls are in, Fig. 23. Inner race and cage will have to be tilted as shown so that each ball can be inserted.
8. Install inner spline housing into outer spline housing, Fig. 24. Raise inner spline housing and install five balls into each spline (six splines, 30 balls).
9. Lower inner spline housing into outer spline housing and install retaining ring into groove at top of outer spline housing.
10. Install retaining ring into inner race, Fig. 25.
11. Pack C.V. joint full of approved lubricant. Pack inside of seal until folds of seal are full.
12. Install seal onto axle shaft.
13. Install O-ring on outer spline housing. Insert axle shaft into splines of inner race until retaining ring secures shaft.
14. Insert drive axle in a press, Fig. 26, and peen seal in six places equally spaced around seal.
15. Remove axle from press. Position seal in groove in axle shaft and pull outward on shaft until inner C.V.

Fig. 13 Removing inner race from ball cage

Fig. 14 Installing balls in outer race

Fig. 15 Installing keystone clamp (large)

Fig. 16 Installing keystone clamp (small)

Fig. 20 Inner spline housing

Fig. 17 Removing or installing inner C.V. joint seal

Fig. 19 Outer spline housing

Fig. 22 Installing inner race into ball cage

Fig. 18 Removing joint from axle

Fig. 21 Installing cover

Fig. 23 Installing balls in inner race

joint is fully extended. *C.V. joint is fully extended before installing keystone seal clamp to prevent a vacuum collapsing seal bellows.*

16. Install keystone clamp and secure, Fig. 27.

FINAL DRIVE, 1968-69

Description, Fig. 28

The final drive assembly, mounted and splined directly to the automatic transmission, consists of a pinion drive gear, a ring gear (bolted to the case), case assembly with two side gears and two pinion gears that are retained to the case with a pinion shaft. A lock pin is used instead of a bolt to lock the pinion shaft to the case. There are thrust washers used behind the side gears and shims behind the pinion gears the same as in a conventional differential. The left side gear is different than the right side gear in that it has a threaded retainer plate to which the left output shaft bolts. The two side bearings are the same and the preload shims are identical for the right and left side. The carrier is identical in external appearance and mounts to the transmission the same as in the past

Fig. 24 Installing balls, inner-to-outer spline housing

Fig. 25 Installing retaining ring

Fig. 26 Staking seal

models.

The output shafts remain identical in external appearance as in the past. The left output shaft has the retainer bolt going through the shaft to the side gear.

FINAL DRIVE, 1966-67

Description, Fig. 29

The final drive assembly, mounted and splined to the automatic transmission, consists of a pinion drive gear, a ring gear and a planetary gear train.

The planetary gear train consists of a planet pinion carrier with three pairs of planet pinions, a sun gear and an internal gear and performs the same function as the side gears and pinion gears in a conventional differential.

Torque from the final drive is transmitted to a right and left output shaft which connect to drive axles. The right output shaft is splined to the sun gear while the left output shaft is splined to the planet pinion carrier.

OUTPUT SHAFT & SEALS

R.H. Shaft, Bearing & Seal

Removal

1. Disconnect battery. Hoist car.

Fig. 27 Installing keystone clamps

Fig. 28 Final drive disassembled. 1968-69

Fig. 29 Final drive disassembled. 1966-67

Fig. 31 Aligning right output shaft

Fig. 33 Final drive attachment. 1966-69

Fig. 32 Output shaft assembled (right side)

2. Remove engine oil filter element.
3. Disconnect R.H. drive axle.
4. Disconnect support from engine and brace.
5. Remove output shaft assembly.

Installation, Figs. 31 and 32

1. If removed, assemble bearing and related parts. Position assembly in a press and install bearing until seated against shoulder on shaft. Pack area between bearing and retainer with wheel bearing grease, then install slinger. Install seal if removed.
2. Install remaining parts removed in reverse order of removal.

L.H. Output Shaft, Bearing & Seal

NOTE: The L.H. output shaft can normally be removed only after removing the final drive assembly from the car. However, if the L.H. drive axle has been removed for any reason, the output shaft and seal can be removed as follows:

1. Remove R.H. output shaft as outlined above.
2. Remove L.H. output shaft retaining bolt and remove shaft.
3. Apply approved lubricant to the seal, then insert output shaft into final drive, indexing splines of shaft with splines on final drive.
4. Install and torque L.H. output shaft retaining bolt to 45 ft-lbs.
5. Install R.H. output shaft in reverse order of removal.

FINAL DRIVE REPLACE

1. Disconnect battery and raise hood.
2. Remove bolts "A", "B", "C" and nut "D", Fig. 33. Nut "D" must be removed with a special wrench. It may be necessary to remove transmission filler tube to obtain clearance.
3. Hoist car. If a two-post lift is used the car must be supported with floor stands at the front frame rails and the front post lowered.
4. Disconnect both drive axles from output shafts.
5. Remove engine oil filter element.
6. Disconnect brace from final drive, then disconnect R.H. output shaft from engine. Remove output shaft from final drive.

Fig. 34 Disconnecting final drive from engine

7. Referring to Fig. 34, remove bolt "X" and loosen bolts "Y" and "Z".
8. Remove final drive cover and allow lubricant to drain.
9. Position transmission lift with adapter for final drive. Install an anchor bolt through final drive housing and lift pad.
10. Referring to Fig. 33, remove bolts "E", "F", "G" and nut "H".
11. Move transmission lift toward front of car to disengage final drive splines from transmission. Provide a container to catch transmission fluid.
12. Lower transmission lift and remove final drive from lift.
13. Using a 9/16" socket, remove L.H. output shaft retaining bolt and pull shaft from final drive.
14. Reverse procedure to install.

Front Suspension & Steering Section

FRONT SUSPENSION

The front suspension consists of control arms, stabilizer bar, shock absorbers and a right and left torsion bar, Figs. 1 and 2. Torsion bars are used instead of conventional coil springs. The front end of the torsion bar is attached to the lower control arm. The rear of the torsion bar is mounted into an adjustable arm at the torsion bar cross member. The riding height of the car is controlled by this adjustment.

LUBRICATION

The steering linkage should be lubricated every 12 months or 12,000 miles, whichever occurs first, using a commercially available multi-purpose grease.

Ball joints should be lubricated and inspected at 36,000 miles (no time limit) and every 12 months or 12,000 miles thereafter, using a commercially available multi-purpose lubricant.

WHEEL ALIGNMENT

NOTE: When checking wheel alignment the car must be on a level surface, gas tank full or a compensating weight added, front seat all the way to the rear, and tires (front and rear) inflated to 24 psi. All doors must be closed and no passengers or additional weight should be in the car or trunk.

1. Check rocker panel to ground dimensions, Fig. 3. Front to rear must be within 1″ and side-to-side within 5/8″ of the dimensions shown.
2. Raise car and check wheel runout. Set in center of runout and lower car.
3. Loosen nuts on inboard side of upper control arm cam bolts, Fig. 4.
4. Check camber and adjust if necessary with the rear cam bolt. Camber reading on the right and left wheel should be within 1/2° of each other.
5. Take a caster reading. If necessary to adjust, turn wheel to straight ahead position. Use camber reading scale for making this adjustment.
   a. Turn rear bolt so camber reading is 1/4° more than the original setting for every one degree of caster change needed for a correct reading. Turn to plus side of camber if caster is negative and to negative camber if caster is positive.
   b. Turn front cam bolt so camber will return to its original proper setting that was made on the camber adjustment.
   c. Recheck caster reading.

NOTE: If a problem exists where you should run out of cam to gain the correct reading, first turn front cam bolt so high part of cam is pointing up. Then turn rear cam bolt so high part of cam is pointing down. This is a location to start from and a correct setting can be obtained with the foregoing procedure. Torque upper control arm cam nuts to 75 ft-lbs. Hold head of bolt securely as any movement of the cam will affect your final setting, which will necessitate a recheck of the camber and caster adjustment.

TOE-IN, ADJUST

1. Center steering wheel.
2. Loosen tie-rod nuts and adjust to proper setting.
3. Tighten tie-rod nuts to 20 ft-lbs. Position tie-rod clamps so opening of clamp is facing up. This is necessary as interference and a possible tie up of front end linkage could occur if clamps snag anything while turning.

TORSION BAR

Removal

1. Hoist car and place floor stands under front frame horns.
2. Slide seat at rear of torsion bar forward.
3. Use a tool of the type shown in Fig. 5.
4. Turn torsion bar adjusting bolt counterclockwise, counting the number of turns necessary to remove. Record this number for installing.
5. Remove adjusting bolt and nut.
6. Turn center screw of tool until torsion bar is completely relaxed.
7. Place block of wood on hoist (6″x6″x8″) and raise under lower control arm until drive axle is horizontal.
8. Remove stabilizer bolt and related parts. Discard bolt.
9. Place a daub of paint on bottom side of torsion bar.
10. Slide torsion bar forward until it bottoms in lower control arm (adjusting arm will drop out). *Do not mar, scratch or in any way damage*

Fig. 1 Front suspension

Fig. 2 Front suspension

Fig. 3 Riding heights

Fig. 4 Front wheel alignment cams

Fig. 5 Removing torsion bar

Fig. 6 Ball joint vertical check

Fig. 7 Pry bar installation

Fig. 8 Ball joint horizontal check

Fig. 9 Installing service ball joint

torsion bar as replacement will be necessary if such conditions exist.

11. Remove crossmember bolt from side torsion bar is being replaced.
12. Remove center bolt from tool.
13. Raise crossmember and twist rearward until torsion bar clears member.
14. Slowly raise lower control arm until maximum height is attained.
15. Raise center crossmember until contact is made with floor pan.
16. Pull rearward on torsion bar with HANDS ONLY until bar is out of lower control arm. *It may be necessary to use air blowing into nut of lower control arm to relieve vacuum caused by grease.*

Installation

NOTE: Check rubber seal for damage; replace if necessary. Check retainer for excessive wear and replace if necessary. A new retainer is required on replacement of torsion bar. Stake as shown in Fig. 1.

Fig. 10 Removing hub assembly

Fig. 11 Drive axle support block

1. Grease both ends of torsion bar for about 3″ with E.P. chassis lube.
2. With daub of paint in same location as when removed, insert bar into lower control arm nut and push forward until bar bottoms.
3. Pry crossmember back and align bar with hole in crossmember.
4. Lower crossmember and install center bolt in tool, Fig. 5.
5. Lower front lower control arm until drive axle is horizontal.
6. Install torsion bar arm and pull bar rearward until fully seated in arm.
7. Install crossmember bolt through rubber mounting and torque to 40 ft-lbs.
8. Lower front lower control arm and remove wood block.
9. Install new bolt in stabilizer bar to lower control arm. Torque to 14 ft-lbs. *Cut off bottom of bolt so that 1/4″ is remaining below nut.*
10. Using the tool shown in Fig. 5 or its equivalent, tighten torsion bar arm to install lock plate under arm and through crossmember.

Fig. 12 Steering gear and shaft

11. Grease threads of torsion bar adjuster with chassis lube and turn into nut the same number of turns required to remove.
12. Remove tool. Lower car to floor.
13. Check riding height, Fig. 3. Correct by turning torsion bar adjusting bolt as required.

BALL JOINT CHECKS

Vertical Check

1. Raise car and place jack stands under both lower control arms as near as possible to lower ball joints.
2. Install dial indicator, Fig. 6.
3. Place a pry bar as shown in Fig. 7 and push down on bar. Use care to see that drive axle seal is not damaged. Reading must not exceed .125".

Horizontal Check

1. With car placed on floor stands, install dial indicator, Fig. 8.
2. Grasp front wheel and rock top and bottom of tire. Read dial gauge, then reverse the push-pull procedure.
3. Horizontal deflection on dial gauge should not exceed .125" at wheel rim. This procedure checks both upper and lower ball joints.

BALL JOINTS REPLACE

Lower Ball Joint

1. Remove knuckle.
2. Hacksaw three rivet heads off.
3. Using a 7/32" drill, drill side rivets 3/16" deep.
4. Drive center rivet until joint is out of control arm.
5. Install service ball joint into control arm and torque bolts and nuts as shown in Fig. 9.
6. Replace knuckle.

Upper Ball Joint

1. Raise car and support on floor stands.
2. Remove wheel and drum.
3. Remove hub assembly, Fig. 10.
4. Remove upper ball joint nut and brake line hose clip from ball joint.
5. Remove anchor bolt.
6. Lift brake plate outward over end of axle shaft and support so brake hose is not damaged.
7. Place support block as shown, Fig. 11.
8. Using a brass drift and hammer loosen and remove ball joint.
9. Install new ball joint and replace parts in reverse order of removal.

WHEEL BEARINGS, REPLACE

(Disc Brakes)

1. Raise car and remove front wheel.
2. Remove drum.

NOTE: For disc brakes remove two bolts securing caliper to steering knuckle and remove caliper.

3. Remove drive axle pin, nut and washer.
4. Position access slot in hub so that each of the attaching bolts can be removed.

NOTE: On disc brakes the attaching bolts are removed from behind the splash shield.

5. Using slide hammer puller, remove hub, Fig. 10.
6. Remove bearing from hub with puller, Fig. 13.
7. Press new bearing into hub.

SHOCK ABSORBER REPLACE

1. Remove upper shock attaching bolt.
2. Remove lower attaching nut and guide shock through upper control arm.
3. Reverse procedure to install.

Fig. 13 Removing front wheel bearing. Toronado

STEERING GEAR REPLACE

1. Referring to Fig. 12, remove coupling flange hub bolt.
2. Disconnect hoses from power steering pump and cap pump and hose fittings. On cars equipped with a cooler disconnect return hose from cooler inlet pipe.
3. Hoist car and pull off pitman arm.
4. Unfasten gear from frame, permit lower shaft to slide free of coupling flange, then remove gear with hoses attached.

NOTE: Before installing steering gear, apply a sodium soap fibre grease to gear mounting pads to prevent squeaks between gear housing and frame. Make sure alignment pin on gear housing enters hole provided in frame side rail. Make sure there is a minimum of .040" clearance between coupling hub and steering gear upper seal.

Install coupling hub bolt and torque to 18 ft-lbs. Before tightening steering gear attaching bolts, shift gear as necessary to place it in the same plane as the steering shaft so that the flexible coupling is not distorted. Tighten gear-to-frame bolts to 70 ft-lbs. and pitman shaft nut to 220 ft-lbs.

5. After hoses are connected to pump, add power steering fluid as necessary to bring the fluid level to the full mark. Run engine at idle for 30 seconds, then run at a fast idle for a minute before turning steering wheel. With engine running, turn steering wheel through its full travel two or three times to bleed air from system. Recheck oil level and add oil if necessary.

PONTIAC

All Intermediate & Full Size Models

OLD CAR SPECIFICATIONS: For 1946-62 Tune Up and Wheel Alignment Specifications see back of book.

Specifications for the 6-215 engine are tabulated on the pages immediately following this index. For service procedure see six cylinder in Chevrolet Chapter.

INDEX OF SERVICE OPERATIONS

PAGE NO.

ACCESSORIES

Air Conditioning 3-41
Automatic Level Controls 1-41
Clock Troubles 1-11
Heater Core, Replace 2-515
Power Top Troubles 1-18
Power Window Troubles 1-18
Radio, Replace 2-515
Speed Controls, Adjust 2-516

BRAKES

Brake Troubles, Mechanical 1-17
Disc Brake Service 1-430
Hydraulic System Service 1-422
Master Cylinder, Replace 2-538
Parking Brake, Adjust 2-537
Power Brake Service 1-440
Power Brake Troubles 1-440
Power Brake Unit, Replace 2-537
Service Brakes, Adjust 2-536

CLUTCH

Clutch Pedal, Adjust 2-529
Clutch, Replace 2-529
Clutch Troubles 1-12

COOLING SYSTEM

Cooling System Troubles 1-6
Variable Speed Fans 1-39
Water Pump, Replace 2-523

ELECTRICAL

Alternator Service 1-63
Clutch Start Switch 2-511
Dash Gauge Service 1-117
Distributor, Replace 2-510
Distributor Service:
Standard 1-53
Transistorized 1-47
Electrical Troubles 1-8
Flasher Location Chart ..... Back Of Book
Generator Service 1-91
Headlamps, Concealed Type 1-40
Horn Sounder, Remove 2-513
Ignition Coils and Resistors 1-24
Ignition Switch, Replace 2-510
Ignition Timing 2-510
Instrument Cluster, Removal 2-513
Light Switch, Replace 2-511
Neutral Safety Switch, Replace 2-511
Spark Plug Condition Chart 2-647
Starter Service 1-101
Starter, Replace 2-510
Starter Switch Service 1-114
Stop Light Switch, Replace 2-511
Turn Signal Switch, Replace 2-511
Turn Signal Troubles 1-11
Windshield Wiper Motor, Replace 2-514
Windshield Wiper Troubles 1-20

WINDSHIELD WIPER

Wiper Motor, Replace 2-514
Wiper Linkage, Replace 2-515
Wiper Switch, Replace 2-515
Wiper Troubles 1-20

SERIAL NUMBER LOCATION

1963-67: On left front door hinge pillar.

1968-69: On plate fastened to upper left instrument panel area, visible through windshield.

ENGINE IDENTIFICATION

The V8 engine code is located beneath the production engine number on a machined pad on the right-hand bank of engine block.

The 6-cylinder engine code is stamped on the cylinder head-to-block contact surface behind oil filler pipe.

①—BTDC: Before top dead center.
②—D: Drive. N: Neutral.
③—Plus or minus 20 lbs.
④—If air conditioned, turn A/C switch to "Full On" position.
⑤—With Air Injection Reactor Emission System (A.I.R.).
⑥—Turn adjusting screw in (clockwise) until engine misfires. Then back off screw ½ turn.
⑦—With A/C off.
⑧—100 R.P.M. higher with A/C off.
⑨—Tempest with manual transmission.
⑩—For service on this engine, see Six Cylinder in Chevrolet Chapter.
⑪—GTO uses R44S; all others use R45S.

①—Stamped on distributor housing plate.
②—As viewed from above.
③—Turn adjusting screw to the right until engine misfires, then turn screw ½ turn to the left.
④—With four barrel carburetor.
⑤—With two barrel carburetor.

ENGINE TIGHTENING SPECIFICATIONS★

★Torque specifications are for clean and lightly lubricated threads only. Dry or dirty threads produce increased friction which prevents accurate measurement of tightness.

①—Tapers from .3414″ top to .3404″.

②—With valve fully closed, turn rocker arm nut down until all play in push rod is eliminated, then tighten nut one additional turn.

③—Intake 30°, exhaust 45°.

④—Outer spring.

⑤—For service on this engine, see Six Cylinder in Chevrolet Chapter.

⑦—No adjustment. On V8's, rocker arms are correctly positioned when ball retainer nuts are tightened to 20 ft.-lbs.

⑧—Intake 29°, exhaust 44°.

⑨—Small valve engines, intake and exhaust 45°. Large valve engines, intake 30° and exhaust 45°.

⑩—Small valve engines, intake 46° and exhaust 44°. Large valve engines, intake 29° and exhaust 44°.

①—Minimum. ②—Includes solenoid.

③—Check capacity of motor by using a 500 ampere meter and a carbon pile rheostat to control voltage. Apply volts listed across motor with armature locked. Current should be as listed.

COOLING SYSTEM & CAPACITY DATA

★NOTE: Alcohol should not be used in Pontiac engines having aluminum components in contact with the coolant (such as the aluminum timing chain cover on 1963-64 engines). When only water is used a good corrosion inhibitor must be added to the system. Failure to use an inhibited coolant may result in severe corrosion damage to the cooling system components.

Electrical Section

IGNITION TIMING

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder is at the ignition timing point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

DISTRIBUTOR, REPLACE

1. Disconnect distributor-to-coil primary wire.
2. Remove distributor cap.
3. Crank engine so rotor is in position to fire No. 1 cylinder and timing mark on vibration damper is indexed with pointer.
4. Remove vacuum line from distributor.
5. Remove distributor clamp.
6. Lift distributor from engine.

Installation

1. Check to see that engine is at firing position for No. 1 cylinder.
2. Install new gasket on block.
3. Install distributor so vacuum unit faces right side of engine and rotor points toward contact in cap for No. 1 cylinder.
4. Install distributor clamp, leaving screw loose enough to allow distributor to be turned for adjustment.
5. Attach vacuum line to distributor.
6. Ins all wires in distributor cap.
7. Attach distributor primary wire.
8. Adjust point gap, replace cap and set ignition timing.

STARTER REPLACE

1965-69 Six-Cyl.

1. Disconnect ground cable at battery.
2. Disconnect cable and wiring harness leads from starter solenoid.
3. Unfasten and remove starter.

1965-69 V8s

1. Disconnect cable from battery.
2. Raise front of car and pull battery cable and solenoid wire loom down so they hang free of surrounding parts.
3. Unfasten and remove starter with cable and solenoid wire loom.
4. Remove wires from solenoid and cable from clamp or solenoid bracket.
5. Reverse procedure to install.

1963-64 Tempest

1. Disconnect ground cable from battery.
2. Disconnect cable and wiring harness leads from starter solenoid.
3. Unfasten and remove starter. *On 4-cylinder engines, use a straight box end wrench through slot in cylinder block casting for the lower mounting bolt.*

1963-64 Pontiac

1. Disconnect battery-to-starter cable from battery.
2. Remove rubber cover from junction block on left fender skirt by pulling straight off.
3. Disconnect junction block-to-solenoid wires from junction block, noting the terminal from which each wire was removed.
4. Remove battery cable from clip on junction block.
5. Raise front of car and place car stand under front suspension.
6. Pull battery cable and solenoid wire loom down so they hang free of surrounding parts.
7. Unfasten and remove starter with cable and solenoid wire loom. *If clearance is insufficient to drop starter, look for worn engine mounts. If worn, remove transmission cross-member to allow removal of starter.*

IGNITION SWITCH, REPLACE

1969

1. Disconnect battery and loosen toe pan screws.
2. Lower steering column from instrument panel.
3. Disconnect switch wires and remove switch.
4. To replace switch move key lock to OFF-LOCK position.
5. Move actuator rod hole in switch to OFF-LOCK position.
6. Install switch with rod in hole.

1963-68

1. Disconnect a battery cable.
2. Remove lock cylinder (see below).
3. Remove ignition switch ferrule by unscrewing it with a suitable spanner wrench.
4. Remove switch lamp housing brace screw from bottom flange of instrument panel.
5. Remove switch from back of panel and disconnect wires after unlatching special locking terminal.
6. Reverse above procedure to install.

Switch Lock Cylinder

1. Place ignition key in lock and depress lock plunger by inserting a small pin through hole in lock cap.
2. While holding plunger in, turn key about 20-deg. counterclockwise to release lock cylinder and remove cylinder from switch.
3. To install, insert key in cylinder. Then with key and cylinder turned about 20-deg. counterclockwise, insert cylinder in lock and rotate clockwise to lock in place.

FREE UP LOCK: Occasionally an ignition lock may stick, making it difficult to insert key and turn lock. If this occurs, blow a small quantity of powdered graphite into the lock key hole and operate key several times until lock operates freely.

If ignition switch will not free up by the use of the graphite, it must be replaced. To remove a stuck lock use a ⅜" drill and drill out the center of the cylinder. The lock tumblers must be destroyed before the cylinder can be removed.

LIGHT SWITCH, REPLACE

1963-69

1. Remove battery cable, pull knob to "On" position, depress latch button and remove knob and shaft.
2. Remove retaining nut.
3. Remove wire connector and remove switch.
4. On vacuum-operated headlight models, remove vacuum connector.
5. Reverse procedure to install.

STOP LIGHT SWITCH, REPLACE

1963

1. Disconnect wires from switch, unfasten switch from bracket and remove it.
2. On cars with power brakes, be sure that brake pedal is in full release position, and position switch so that approximately $\frac{3}{16}$" of the plunger extends from the switch body.

CAUTION: On cars without brake booster, if stop light switch or pedal bracket prevents full return of pedal and master cylinder push rod, the master cylinder piston may be prevented from returning to its stop. This can block off the compensating port which prevents brake shoes from returning fully when pedal is released. A further complication which follows a blocked compensating port is lining drag and complete brake burn-up on the first prolonged drive. It is necessary that the master cylinder primary cup be entirely clear of the compensating port to provide a safety factor against normal rubber swell and expansion and deflection of body parts and pedal linkage.

Therefore, after changing pedal height or stop light switch, adjust switch, being sure brakes fully release after adjustment is made.

Fig. 1 Turn signal control. 1963-65 Pontiac

1964-69

The stop light switch has a slip fit in the mounting sleeve which permits positive adjustment by pulling the brake pedal up firmly against the stop. The pedal arm forces the switch body to slip in the mounting sleeve bushing to position the switch properly.

1. Disconnect wires from switch and remove switch from bracket.
2. Position switch in bracket and push in to maximum distance. Brake pedal arm moves switch to correct distance on rebound. Check if pedal is in full return position by lifting slightly by hand.
3. Connect switch wires by inserting plug on switch.

NEUTRAL SAFETY SWITCH

1969

1. To replace switch, position shift tube in drive position.
2. Insert switch drive tang in shifter tube slot and assemble switch to column jacket.
3. To adjust switch, position and hold shift lever in low range while inserting blade of reset gauge J23056-2 into the RESET slot of switch. Be sure the tool is inserted about $\frac{9}{16}$".
4. Insert blade of gauge J22701-5 into ADJUST slot of switch and move shift lever to park position and remove gauge.
5. Check starter in all ranges.

Fig. 2 Turn signal control disassembled. 1963-65 Pontiac

1963-68

Properly adjusted the switch should turn on the back-up lights in reverse and prevent engine cranking with the selector lever in any position other than Park or Neutral. If the engine cranks in any other position, adjust by loosening the mounting screws and repositioning as required.

If console shift, adjust switch adjusting screw.

On 1967 Pontiac, GTO and Firebird, rivet heads must be removed and rivets punched through into column to remove switch. Replace rivets with ¼ x $\frac{7}{32}$" self-tapping screws. *Screws must not be larger than ¼" or damage to column may result.*

CLUTCH START SWITCH

1969

All cars equipped with a manual transmission use a clutch start switch which is mounted on the brake bracket. The switch closes when the clutch is depressed and completes solenoid connection. When installing switch, no adjustment is necessary.

TURN SIGNAL SWITCH

1969

NOTE: On tilt column, the column must first be lowered from panel.

1. Remove steering wheel using puller. *Caution: Do not hammer on end of shaft as hammering could collapse shaft or loosen plastic injections which maintain column rigidity.*
2. Remove three cover screws and lift cover off shaft. **NOTE:** Screw retainers will be lost if screws are removed completely from cover.
3. Depress lock plate and pry round wire lock ring out of shaft groove.
4. Slide upper bearing preload spring and turn signal cancelling cam off shaft.
5. Slide thrust washer off shaft and remove turn signal lever.
6. Push hazard warning switch in and unscrew knob.
7. Pull turn signal wiring connector out of bracket on jacket and disconnect.
8. Remove three turn signal switch screws and pull switch straight up.

1967-68 Non-Tilt Column

1. Remove steering wheel. *Caution: Do not hammer on steering shaft as column jacket could be collapsed.*
2. Remove upper bearing preload spring and turn signal cancelling cam off steering shaft.

3. Remove turn signal lever screw and lever. On Tempest and Firebirds with automatic transmission and column shift, remove shift indicator bezel by removing two clips between bezel and inside of switch cover.
4. Push in hazard warning knob and unscrew knob. On 1967, remove turn signal cover, switch retaining screws and switch. On 1968, proceed with disassembly.
5. Remove snap ring from upper steering shaft by sliding sideways out of groove. Do not pry against switch.
6. Slide thrust washer and wave washer off upper steering shaft.
7. Disconnect turn signal switch wiring harness at connector under instrument panel.
8. Remove steering column mounting bracket to provide clearance so that wiring and curved connector can be removed.
9. Pry wiring harness cover off steering column and allow wiring harness to hang free.
10. Position mounting bracket back under instrument panel and install two nuts holding bracket to instrument panel.
11. Loosen three switch mounting screws until cover can be rotated counterclockwise. It may be necessary to push on top of screws to loosen. Rotate cover counterclockwise and pull straight off top of jacket.
12. Remove three mounting screws completely from engagement with the lock plate. Be careful of the three springs which may be lost during this action.
13. Pull switch and housing from cover.
14. Reverse procedure to install.

1967-68 Tilt Column

1. Remove steering wheel. *Caution: Do not hammer on steering shaft as column jacket could be collapsed.*
2. Remove turn signal cancelling cam and cam spring.
3. Remove tilt release lever and turn signal lever. On Tempest and Firebird with automatic transmission and column shift, remove shift indicator bezel (2 screws each side of bezel).
4. Push in hazard flasher knob, remove knob and turn signal cover. On 1967, disconnect and remove switch and harness. Cut signal harness to allow removal of switch. *NOTE: A wire or string attached to wires of harness when pulled through will aid in re-assembly.* On 1968, proceed with disassembly.
5. Remove steering column mounting bracket. With mounting bracket removed, pry wiring harness off steering column and allow wiring to hang free.
6. Position mounting bracket back underneath instrument panel and install two nuts attaching bracket to panel.
7. Unplug wiring harness from body harness and disconnect curved connector from wiring harness. Be sure to note exact location of each wire prior to removing from connector body.

Fig. 3 Turn signal switch. 1963-65 Pontiac

8. Remove three turn signal attaching screws and withdraw a wiring harness from steering column.
9. Reverse procedure to install.

1963-65 Pontiac

Regular Column

The turn signal actuator is located in a housing just below the steering wheel, Fig. 1. The turn signal switch is mounted on the steering column jacket, Fig. 3. It is actuated by a rod inside the steering column jacket, Fig. 4.

1. Disconnect horn cable from terminal.
2. Remove wires from switch terminal.
3. Unfasten switch from steering column housing (2 screws) and hold wire retainer from steering column housing.
4. Hold actuator rod anti-rattle coil spring and bearing plate and remove hair-spring type actuator lever from actuator rod, Fig. 4. *A rag stuffed into the opening below the actuator rod will prevent loss of actuator spring.*
5. Remove anti-rattle spring and bearing plate.
6. Remove steering wheel and pull actuator rod out from top end of steering column.
7. Pull horn connector assembly and horn wire from end of upper bearing support plate.
8. Remove actuator housing (3 screws), Fig. 2. Actuator can be removed from housing by removing control lever and pressing out shield.

Fig. 4 Details at lower end of actuator rod. 1963-65 Pontiac

Installation

1. Install horn wire and contact assembly in end of bearing support, Fig. 5, snaking wire through outer slots of bearing support lock plate and retainer plate, and between steering column housing and shifter tube.

NOTE: Attaching a suitable firm wire to end of horn wire will simplify installation of horn wire into steering column.

2. Pull end of horn wire out appropriate opening in steering column housing.
3. Install actuator housing over upper bearing support and insert 3 screws.
4. Install actuator rod bearing plate, signal switch and horn wire retainer in position on housing, Fig. 4. Insert two screws and star washers but do not tighten.
5. Insert actuator rod through opening in actuator housing and engage lower end of rod in hole in bearing plate.
6. Engage top end of actuator rod in slot of actuator housing.
7. Install anti-rattle spring on lower end of actuator rod.
8. With turn signal switch carrier in neutral, insert a $\frac{3}{32}''$ gauge pin into two holes in switch bracket and install actuator lever, engaging lever on prong of switch.
9. Tighten switch retaining screws, being certain that there is no tension on actuator rod when screws are tightened.
10. Insert horn wire through retainer.

NOTE: When installing turn signal switch it is very important that it be centered properly on steering column. Improper position can result in an inoperative stop light.

Tilt Column

1. To remove switch, remove wiring connector and switch from steering column.
2. Loosen screw and remove control cable from switch, Fig. 6.
3. To install, hook control cable wire over actuating pin on switch. Place control lever in neutral.
4. Move carrier in switch to neutral.
5. Lock cable clamp screw.

NOTE: The ability of this screw to tighten the clamp depends on the angular direction the screw takes when initially driven. If the screw head bearing is toward the clamp hinge, it will probably not hold the control cable housing. This definitely affects switch adjustment. When the clamp does not hold the cable with the screw properly tightened, the clamp should be bent to close the normal gap.

6. While holding switch in normal position, start the two switch mounting screws.
7. Recheck to make certain that lever and switch are still in neutral, then tighten the screws.

1966 Pontiac

Regular Column

1. Remove steering wheel.
2. Remove spring and cam assembly.
3. Unscrew lever from switch.
4. Remove shift lever and spring by removing pivot pin and shim.
5. Disconnect horn wire and turn signal connector.
6. Remove lower trim cover plate.
7. Remove screw which retains washer assembly to column jacket.
8. Remove 3 screws from turn signal housing and lift bearing and turn signal switch from housing.
9. Rotate turn signal housing counterclockwise and lift off.
10. Remove flat washer.
11. Slide off gearshift lever housing. *On cars with automatic transmission, remove screw and washer that retains tube assembly to shift lever housing.*
12. Remove spacers, washers and sleeve.
13. Reverse procedure to install.

NOTE: After new turn signal switch has been installed to turn signal housing, the wire harness must be inserted through gearshift housing and sleeve before these parts are installed over column assembly.

Tilt Column

1. Remove wiring connector and switch from steering column.
2. Loosen screw and remove control cable from switch.
3. To install, place steering wheel in "pull-down" position.
4. Place switch lever in neutral.
5. Hook control cable wire over actuating pin on switch.
6. Move carrier in switch to neutral position.
7. Lock cable by tightening clamp screw.
8. Locate circuit switch on steering column mast jacket so there is no slack in conduit. Start two mounting screws. *Do not pull on switch so as to extend switch slide screw.*
9. Make certain that lever and switch are still in neutral, then tighten two switch mounting screws.

1963-65 Tempest

1. Remove steering wheel and disconnect horn wire lead and turn signal connector.
2. Rotate turn signal housing on steering column jacket and remove housing.
3. Reverse above procedure to install.

1966 Tempest

1. Remove steering wheel.
2. Remove spring and cam assembly.
3. Remove lever from switch.
4. Remove lever retaining pin and lever.

Fig. 6 Tilt wheel turn signal switch. 1965 Pontiac

5. Disconnect horn wire and turn signal connector.
6. Remove 2 screws from lower trim cover plate.
7. Remove column bracket so wire loom can slide through.
8. Remove wiring cover.
9. Remove 3 screws on upper bearing and turn signal switch.
10. Remove signal and housing, and shift lever housing from steering jacket. *Signal housing will need to be rotated.*
11. Remove turn signal from signal and shift lever housing.
12. Reverse procedure to install.

NOTE: Turn signal control assembly must be in neutral position when installing steering wheel to prevent damage to cancelling cam and control assembly.

HORN SOUNDER & STEERING WHEEL

1965-69

1. Lift ornament out of wheel hub.
2. Remove nut and washer from shaft. On 1966 Tempest, remove spacer bushing.
3. Remove horn bar (deluxe wheel) or extension and switch assembly (standard wheel).
4. Use a suitable puller to remove wheel.
5. Reverse procedure to install, making sure wheel is in straight ahead position.

1963-64

Standard Wheel

1. Pry out horn button.
2. Remove three screws and insulators and remove button retainer.
3. Remove contact ring, pivot contact, spring and insulator.
4. Remove lock nut, retaining nut and washer from steering shaft.
5. Remove contact plate.
6. Remove wheel with puller.

Deluxe Wheel

1. Twist steering wheel ornament and lift to remove.
2. Remove lock nut, retaining nut and washer from steering shaft.
3. Remove horn ring and contact assembly.
4. Remove contact assembly from horn ring (3 screws).
5. Remove pivot contact, spring and insulator from hub of wheel.
6. Use puller to remove wheel.

INSTRUMENT CLUSTER

1969 Grand Prix

1. Disconnect battery and remove glove box.
2. Disconnect speedo cable and wire connectors at headlight switch, wipers, turn signal, ignition switch, printed circuit, heater and air conditioner panel.
3. Remove lower column trim and disconnect air control cable at heater case.
4. Remove screws at instrument locations and instrument panel to column support.
5. Remove screws at outboard lower ends of panel.
6. Remove screws retaining right and left side of instrument panel to body. To do this, remove upper vent nozzles by inserting two thin blade screwdrivers on right and left side of nozzle to disengage retaining clips.
7. Remove upper instrument panel cover plate. Studs are pushed into retainers, pry up carefully to remove.
8. Remove two upper panel retaining screws and upper speaker support bracket screw.
9. Remove console to instrument panel screws.
10. Loosen toe plate screws.
11. Remove column to lower panel retaining nuts and lower column.
12. Pull entire instrument panel rearward on left far enough to gain access to cluster.
13. Remove ground strap screws and panel harness retaining screws.
14. Remove cluster retaining screws and remove cluster.

1969 Pontiac

1. Disconnect battery.
2. Remove lower instrument panel cover and remove radio.
3. Remove heater or air conditioning control panel.
4. Disconnect speedometer, printed circuit connector, cigar lighter and instrument panel harness from rear of cluster.
5. Remove four cluster retaining screws.
6. Position ground straps so that cluster may be pulled from studs and removed towards center of car.

1969 Tempest

1. Disconnect battery and remove glove box.
2. Disconnect speed cable and wire connectors at light switch, wiper, turn signal, ignition switch, printed circuit, heater and air conditioning control panel.
3. Remove lower column trim and disconnect air control cable at heater case.

4. Remove three screws at instrument locations.
5. Remove two screws at instrument panel to column support, one screw at each outboard lower end of panel and three nuts above glove box (inner).
6. Loosen two right hand toe plate screws and two screws clamping right toe plate to left toe plate.
7. Remove column to instrument panel bracket nuts and lower column.
8. Pull entire instrument panel rearward far enough to gain access to cluster.
9. Remove ground strap screws and two panel harness retaining screws.
10. Remove cluster retaining screws and remove cluster

1969 Firebird

1. Disconnect battery and remove lower instrument panel cover.
2. Remove ash tray bracket screws and radio retaining nuts and glove box.
3. Disconnect heater control cables and wire connectors.
4. Disconnect speedo cable and remove upper L. H. vent duct connector.
5. Disconnect headlamp switch shaft.
6. Remove screws across top and bottom of instrument plate and nut on right side (stud through steel portion of dash).
7. Drop steering column by loosening toe plate screws and removing lower column support nuts.
8. Protect top of column and pull panel rearward to rest on column.
9. Disconnect printed circuit accessory, wiper and cigar lighter.
10. Remove ground strap, cluster retaining screws and carefully remove cluster.

1968 Tempest

1. Disconnect battery.
2. Remove instrument panel fore pad.
3. Disconnect speedometer cable, main wire and switch connectors.
4. Remove instrument panel trim panel retaining screws and disconnect heater control.
5. Remove mast jacket upper retaining screws, lower column and remove trim panel.
6. Remove cluster retaining screws and take out cluster.
7. Reverse procedure to install.

1967-68 Firebird

1. Disconnect battery ground cable.
2. Remove mast jacket lower support screws at toe pan.
3. Remove mast jacket upper support bolts and allow steering wheel to rest on seat cushion. Both supports must be detached to prevent distortion of mast jacket.
4. Remove screws from face of panel and partially remove cluster from console opening.
5. Reach behind cluster and disconnect speedometer cable, speed warning device (if equipped) and chassis harness connector at rear of panel.
6. Remove cluster from console opening.
7. Reverse procedure to install.

1963-65 Pontiac Speedometer Cluster

1. Disconnect Safeguard control cable on cars so equipped.
2. Remove speedometer cluster.
3. Remove cluster face plate and lens by unsnapping face plate from housing.
4. Remove three screws on back of cluster at cable area.
5. Remove speedometer and instruments. If equipped with Safeguard speedometer, disconnect ground wire at clip terminal and also wire retainer clip. Carefully note routing of wires before removing ground wire.
6. Remove two screws retaining numeral plate and remove speedometer.

1966 Pontiac Speedometer Cluster

1. Disconnect Safeguard control cable (if equipped).
2. Remove speedometer cluster.
3. Remove cluster face plate and lens by unsnapping face plate from housing.
4. Remove screws on back of cluster at speedometer fitting area.
5. Remove speedometer and instruments carefully.

NOTE: If equipped with Safeguard speedometer, disconnect ground wire at clip terminal and also wire-retaining clip. Carefully note routing of wires before removing ground wire.

---

6. Remove two screws retaining numeral plate and remove speedometer head.
7. Reverse procedure to install.

1967-68 Pontiac

1. Disconnect battery.
2. Remove instrument panel pad.
3. If equipped with front speaker, disconnect speaker wire.
4. Remove two bolts on each end of instrument panel trim plate.
5. On A/C cars remove lower duct assembly.
6. Remove bolts connecting instrument panel trim plate and lower instrument panel.
7. If equipped with automatic transmission, remove column cover and shift indicator.
8. On models with headlamp doors, it may be necessary to disconnect vacuum lines from headlight switch.
9. On models with upper level ventilation system, remove pipes connecting to nozzle assembly.
10. If radio equipped, remove bolt from radio-to-radio support brace.
11. If equipped with Safeguard speedometer, buzzer must be detached.
12. Disconnect "feeder" of fiber optic system from cigar lighter.
13. If equipped with Multiplex, disconnect unit.
14. Disconnect speedometer.
15. Pull instrument panel plate forward. *Make sure all wires and routing clips are loose enough to allow panel to come forward.*
16. Disconnect wires attaching to instrument cluster.
17. Detach cluster from panel trim plate (4 nuts).
18. Remove cluster.
19. Reverse procedure to install.

1967 Tempest

1. Disconnect battery.
2. Remove 10 screws retaining bezel and cluster assembly to instrument panel.
3. Remove speedometer cable.
4. Disconnect heater control cables.
5. Lower steering column by removing trim plate and loosening nuts on column bracket.
6. Pull cluster and bezel out from instrument panel opening to gain access to wiring and other connections.
7. Starting at top, remove bulbs, wiring and other connections as necessary.
8. Remove screws retaining cluster to bezel and remove cluster.
9. Reverse procedure to install.

1964-66 Tempest

1. To remove cluster, disconnect battery. Then remove 10 screws retaining bezel and cluster to panel.
2. Remove speedometer cable.
3. Pull cluster and bezel out from panel opening to gain access to wiring.
4. Starting at top, remove bulbs and wiring.
5. Remove four screws retaining cluster to bezel and remove cluster.
6. Service instruments as required and install in reverse order of removal.

1963 Tempest

1. Disconnect battery and remove left air conditioning duct (if equipped).
2. Remove retaining nuts.
3. Remove speedometer cable.
4. Pull cluster and housing out from panel opening to gain access to wiring.
5. Starting at the top, remove bulbs and wiring.

W/S WIPER MOTOR, REPLACE

1969

1. Remove hoses and wires connected to wiper.
2. On Pontiac, remove retainer securing wiper crank to transmission linkage. This can be done by removing plastic plug from left side of upper shroud, above wiper motor.
3. On Tempest and Grand Prix, remove screen and loosen clamp securing wiper crank to linkage.
4. Remove screws securing wiper assembly to dash.
5. On Firebird, carefully pull wiper assembly away from firewall until retainer securing wiper crank to transmission can be removed.
6. Remove wiper motor.

1963-65 Pontiac & 1966-68 All

1. Remove hoses and wire terminals connected to wiper unit.
2. On Pontiac models, remove retainer

securing wiper crank to wiper transmission linkage. This can be done by removing plastic plug from left side of upper shroud, directly above wiper motor.
3. On Tempest Optional System models, remove screen and remove retainer securing wiper crank to wiper transmission linkage.
4. Remove screws securing wiper assembly to firewall.
5. On Tempest and Firebird models, carefully pull wiper assembly away from firewall until retainer securing wiper crank to wiper transmission arm can be removed.
6. On Tempest models, remove arm.
7. Remove wiper motor from firewall.
8. Reverse procedure to install.

1963-65 Tempest

1. Remove wire terminals from motor.
2. Remove retainer securing wiper crank to transmission arm. This connects inside car at fire wall under instrument panel.
3. Remove motor from fire wall.

W/S WIPER TRANSMISSION, REPLACE

1963-69

1. Remove wiper arms and blades.
2. Remove fresh air intake screen or grille.
3. Remove wiper transmission screws.
4. On Pontiac models, remove center support screws.
5. On Depressed Park Optional System models, remove retainer securing linkage that attaches to wiper motor crank. On Pontiac models, this can be done by removing plastic plug from left side of upper shroud, directly above wiper motor.
6. On Tempest models, remove retainer securing right wiper transmission to linkage that attaches to wiper motor crank.
7. Remove transmission and linkage.
8. Reverse procedure to install.

W/S WIPER SWITCH

1969 Pontiac, Tempest & Grand Prix

1. Disconnect battery and wire from switch.
2. Remove retaining nuts.
3. Position ground straps and remove switch.

1969 Firebird

1. Disconnect battery.
2. Remove upper vent duct.
3. Remove switch retaining screws and reposition ground straps.
4. Remove switch.

1963-68

1. Loosen Allen screw and remove knob.
2. Remove nut securing shaft and bezel.
3. Remove switch and disconnect terminals.
4. On models with vacuum headlight doors, disconnect vacuum lines.
5. Reverse procedure to install.

RADIO REPLACE

NOTE: When installing radio, be sure to adjust antenna trimmer for peak performance.

1969

1. Disconnect antenna and wires from radio.
2. Remove knobs, springs, nuts and bezels from control shafts.
3. Remove screws securing radio to dash or to brace and carefully remove radio.

1967-68 Firebird

1. Remove tape player and/or Multiplex Adapter (if equipped).
2. Remove radio knobs, bezels, nuts and radio trim plate.
3. Remove ash tray.
4. Remove four screws from lower edge of instrument panel trim plate (two retain ash tray housing). Remove trim plate by pulling bottom of plate outward to disengage from plastic retainer at top of instrument panel.
5. On A/C cars, remove right and left hand hoses from distribution ducts to instrument panel outlets. Remove center distribution duct and left hand plenum together.
6. Remove ash tray housing.
7. Disconnect all radio leads.
8. Remove radio brace to radio screw.
9. Remove two screws at sides of radio controls and lower radio out left side of instrument panel.
10. Reverse procedure to install.

1967-68 All

1. Remove stereo tape player (if equipped).
2. Remove knobs, springs, nuts and bezels from control bushings.
3. If equipped with A/C, remove three Phillips head screws holding bottom A/C air duct and remove duct.
4. Disconnect stereo multiplex plug from radio (if equipped).
5. Remove antenna lead-in and speaker connector.
6. Remove hex screws holding right side of radio to brace.
7. Disconnect dial light socket and lower radio.
8. Remove Multiplex Adapter (if equipped).
9. Reverse procedure to install.

1963-65 Pontiac

1. Remove glove compartment, control knobs and large hex nuts.
2. Remove nut and washer from radio support bracket on left side of radio.
3. Remove radio-to-fuse block wire, antenna lead in wire and speaker leads.
4. Remove radio through glove compartment door.

1966 All

1. Remove knobs and springs and ⅝" hex nuts from control bushings.
2. On Pontiac, remove A/C duct if so equipped. On Tempest with A/C, remove glove box.
3. On all models, remove hex screw from radio mounting bracket.
4. Remove antenna and speaker connectors.
5. Remove dial light socket from radio before "dropping" radio to floor area.
6. Reverse procedure to install.

NOTE: On AM models, remove dial light socket from radio and remove radio through glove box.

On AM-FM models, remove two $\frac{5}{16}$" screws from under dash mounted nozzles (passenger and driver side). Remove auxiliary nozzle, air distributor and center air duct. Remove dial socket and lower radio to floor.

1963-65 Tempest

1. Remove control knobs, retaining nuts and escutcheons.
2. Disconnect antenna and speaker leads.
3. Remove lamp wire assembly (top of radio on push button models; bottom of radio on manual units).
4. Remove support-to-bracket bolt and lift out radio.

NOTE: On custom air conditioned cars it will be necessary to remove the cold air distributor duct.

HEATER CORE REMOVAL

1969

1. Drain radiator and remove heater hoses at their connections beside air inlet assembly.
2. Remove five nuts from core case studs on engine side of dash.
3. Inside the car, pull entire heater assembly from firewall.
4. Remove cables and all electrical connectors from heater and remove heater. On Grand Prix, remove vacuum hoses.
5. Remove core tube seal and core retaining strips and remove core.

1965-68 Full Size Models

1. Disconnect temperature control cable on top of heater.
2. Disconnect vacuum hose from defroster and air inlet diaphragms.
3. Remove wire connector from resistor on top of air outlet duct by prying it up with a flat-blade screwdriver.
4. Unfasten air inlet duct from heater.
5. Heater core can now be removed.

1968 Firebird

1. Remove nuts from heater core case on engine side of dash.
2. From inside vehicle, pull heater from under dash and remove bowden cables and all electrical connectors.
3. Lift out assembly and remove core tube seal and core retaining springs and lift out heater core.

1965-68 Intermediates Except 1968 Firebird

1. Remove glove box.
2. Remove five nuts retaining heater case to dash.
3. Pull case from dash and disconnect all cables and the wire connector from heater resistor.
4. Heater core is now exposed and easily removed.

1963-64 Full Size Models

1. Disconnect vacuum and water hoses at heater.
2. Remove inlet case and sleeve.
3. Remove glove box and disconnect cable, wiring, vacuum and defroster hoses.
4. Remove spring retainer on heater core stud at engine side of dash.
5. Remove heater core from beneath instrument panel.

1964 Tempest

The heater case is removed from the passenger side of the dash and is secured to the air inlet assembly with six nuts.

1963 Tempest

1. Remove heater blower motor.
2. Disconnect necessary cables, wiring and hoses at heater case, and remove case.
3. On bench, remove four screws at front of duct, then remove screws that retain temperature control valve to duct.
4. Disconnect temperature sensing tube from heater core and remove core and valve.

SPEED CONTROLS

1969 Cruise Control

Brake Release Switch, Adjust

Apply brake pedal and push both switches forward as far as possible. Pull pedal forcibly rearward to adjust switches.

Chain Linkage, Adjust

1. Start engine and set carburetor to hot idle position.
2. Thread bead chain through hole in carburetor lever extension.
3. Adjust bead chain at extension to provide minimum slack and assemble clip to extension by straddling extension.
4. A minimum of two beads must extend outside of clip after adjustment.

Fig. 7 Centering spring adjustment. 1967-69 Cruise Control

Cut off excess chain.

Centering Spring, Adjust

If speed control holds speed three or more mph higher than selected speed, turn centering screw (C) clockwise ⅛ turn or less, Fig. 7.

If speed control holds speed three or more mph below selected speed, turn centering adjustment screw (C) counterclockwise ⅛ turn or less. *Do not move adjustment screw* (R).

1967-68 Cruise Control

Brake Release Switch, Adjust

1. Disconnect multiple connector at regulator.
2. Turn ignition switch to accessory position.
3. Using a test lamp, ground one test lamp lead and touch the other to terminal No. 2 in harness connector.
4. Adjust switch so that lamp will light when brake pedal is fully released and will go out when brake pedal is depressed about ¼ inch.
5. If switch cannot be adjusted, it is defective and should be replaced. Install new switch and repeat Step 4.
6. Remove test lamp, turn off ignition key and plug connector to regulator.

Chain Linkage, Adjust

Chain linkage should never be taut. To adjust, start engine, set carburetor at hot idle with anti-stall plunger backed off so as not to affect engine idle speed. Hook chain to accelerator linkage, pull taut, then loosen by length of one ball and install chain clip. *When pulling chain taut, do not pull so far as to cause throttle to open.*

Centering Spring, Adjust

If speed control system holds speed three or more mph higher than selected speed, turn centering spring adjusting screw (C) toward (S) $\frac{1}{32}''$ or less, Fig. 7.

If speed control system holds speed three or more mph below selected speed, turn centering spring adjusting screw (C) toward (F) $\frac{1}{32}''$ or less. *Do not move adjustment screw (R).*

1964-66 Electro Cruise

Power Unit Ball Chain, Adjust

IMPORTANT: Do not lubricate power unit ball chain or its pulley.

1. Loosen jam nut on threaded stud attached to end of ball chain.
2. With carburetor set on slow idle cam, rotate threaded stud so that chain is just taut without advancing idle speed of engine with engine running, then back off one full turn.
3. Tighten jam nut against rivnut on throttle bracket.
4. This adjustment should always be checked whenever carburetor linkage is adjusted.

Brake Release Switch, Adjust

1. Disconnect wiring harness connector from brake release switch.
2. Connect test lamp across switch terminals.

NOTE: If desired, the cruise lamp in the engagement switch may be used as a test lamp by unplugging connector to speed transducer in speedometer and leaving release switch wiring connector on switch. Then turn ignition switch on and press control knob which will cause Cruise light to be on.

3. Loosen screw that retains switch to brake pedal support bracket. Position switch to open the circuit at ½ inch brake pedal travel. An open circuit will be indicated by an unlit test lamp. If Cruise lamp is used, an open circuit will be indicated when light goes out.
4. When brake pedal is at released position, the circuit must be closed for the Electro-Cruise to operate.
5. Tighten adjusting screw and recheck switch adjustment by depressing brake pedal several times with test lamp connected.
6. Readjust as necessary and reconnect wiring harness.

Conventional Engine Section

See page 2—524 for the Overhead Camshaft Engine

For service on 6-215, see Six Cylinder in Chevrolet Chapter

ENGINE, REPLACE

1964-69 Pontiac & 1967-69 Tempest & Firebird V8

1. Scribe alignment marks around hood and remove hood.
2. Disconnect engine wiring harness and engine-to-body ground straps.
3. Remove air cleaner and fan shield.
4. If equipped with manual transmission, remove radiator.
5. With power steering or air conditioning, remove pump and compressor from mounting brackets and set aside. Do not disconnect hoses.
6. Remove engine fan and pulley.
7. Disconnect accelerator control link-

age and linkage support bracket.
8. If equipped, disconnect automatic transmission vacuum modulator line and power brake vacuum line at carburetor and fold back out of the way.

NOTE: On Firebird with A/C, remove wiper motor.

9. Raise vehicle and drain crankcase.
10. Disconnect fuel lines and exhaust pipes.
11. Disconnect starter wires.
12. With automatic transmission, remove converter cover, converter retaining bolts and slide converter to rear.
13. With manual transmission, disconnect clutch linkage, remove clutch cross shaft, starter and lower flywheel cover.
14. Remove lower bell housing bolts.
15. Remove front engine mounts at frame.
16. Lower vehicle.
17. Using jack and block of wood, support transmission.
18. Remove remaining bell housing bolts.
19. Raise transmission slightly. Then, using suitable lifting equipment, remove engine.
20. Reverse procedure to install.

1963 V8s

In addition to the usual items such as radiator, hood, battery, propeller shaft, lines and linkage, it will be necessary to perform the following operations:

1. Disconnect exhaust pipe from crossover pipe.
2. On manual shift cars, disconnect linkage from clutch and remove clutch control countershaft bracket from flywheel housing.
3. Thread a chain through openings in intake manifold behind carburetor.
4. Attach chain to a hoist and raise engine just enough to take weight off mounts.
5. Unfasten mountings from crossmembers.
6. On Hydra-Matic cars, support transmission with a jack and remove frame crossmember to which rear engine mounts are fastened.
7. Hoist engine and transmission as a unit.
8. Reverse above procedure to install. However, on Hydra-Matic cars it will be necessary to raise rear of engine to install the crossmember.

SERVICE BULLETIN

PROTECTS ENGINE SUPPORT: Whenever the engine is raised to facilitate a service operation, be sure to loosen the two lower bolts that secure the rear engine support. Do not completely remove the nuts. For safety, loosen the nuts until they are retained only by the last few threads.

Failure to loosen the mount may damage the insulator when the engine is raised. This will result in a metal-to-metal contact, which can cause vibration or a sound similar to a gear rattle in the transmission.

1964-69 Six & 1964-66 Tempest V8

NOTE: The engine and transmission are removed as a unit. First disconnect and/or remove as required wires, tubes, hoses and linkage attached to engine and transmission. Then perform the following:

1. Remove hood, radiator and fan.
2. Remove drive shaft.
3. Remove four lower transmission mounting bolts.
4. Disconnect exhaust pipe from engine.
5. Remove starting motor.
6. Loosen engine front mounting bolts.
7. Remove engine and transmission as a unit, using suitable lifting equipment.
8. Remove engine and transmission as an assembly.

1963 Tempest

1. Remove hood, radiator and heater hoses at engine.
2. Disconnect wiring harness at engine units, engine ground straps, fuel line at fuel pump, vacuum modulator line at transmission hose connection, accelerator rod at engine lever and exhaust pipe at manifold.
3. Remove front fender cross brace and fan and pulley.
4. Raise front of car and place wood block at rear of engine to prevent damage to distributor if engine rocks to rear.
5. Disconnect propeller shaft and torque tube from rear of engine and disconnect engine support at crossmember.
6. Raise engine and move forward to clear firewall and heater.
7. Reverse removal procedure to install the engine. *However, be sure to follow instructions for installing the propeller shaft as outlined in the Propeller Shaft Section. Failure to follow procedure may result in damage to drive line.*

CYLINDER HEAD

NOTE: Pontiac recommends no numerical sequence for tightening cylinder heads. However, they may be tightened by starting at the center bolts and then working alternately from side to side and outward toward the ends.

4-195 Engine

1. Remove intake manifold.
2. Disconnect breather pipe or hose from vent valve and remove push rod cover.
3. Remove bolts attaching exhaust manifold to head.
4. Remove rocker arm cover.
5. Loosen rocker arm nuts and rotate rocker arms so push rods can be removed.
6. Lift out push rods and tag them so they can be reinstalled in original locations.
7. Remove head bolts and lift off head.

Engine oiling system. V8s

Engine oiling system. Four Cylinder engine

Fig. 1 Installing rocker arm stud without removing cylinder head. 1963-68 engines with push rod oiling

8. Note that there are three different length bolts used. When installed properly, they will project an equal amount from their bosses. Do not use sealer on bolt threads. When installed, tighten rocker arm nuts to 15-25 ft. lbs. torque.

V8 Engines

1. Remove intake manifold, push rod cover and rocker arm cover.
2. Loosen all rocker arm nuts and move rocker arms off push rods.
3. Remove push rods, keeping them in order so they may be installed in their original locations.
4. Detach exhaust crossover pipe from manifolds.
5. Remove battery ground strap and engine ground strap on left head or engine ground strap.
6. Unfasten and remove head with exhaust manifold attached.

CAUTION: Use extreme care when handling heads as the rocker arm studs are hardened and may crack if struck.
NOTE: If left head is being removed, it will be necessary to raise head off dowel pins, move it forward and "jockey" it in order to clear power steering and power brake equipment if so equipped.

7. Reverse removal procedure to install the heads.

NOTE: On V8-326 engines, bolts are three different lengths. When inserted in proper holes all bolts will project an equal distance from the head. Do not use sealer of any kind on bolt threads.

ROCKER ARM STUDS

1967-69 V8 With Screw in Stud

1. Remove rocker arm cover.
2. Remove rocker arm and nut.
3. Using a deep socket, remove rocker stud.
4. Install new stud and tighten to 50 ft. lbs.
5. Install rocker arm and tighten nut to 20 ft. lbs.
6. Install rocker cover using new gasket.

1963-69 V8 With Push Rod Oiling - Pressed in Stud

NOTE: Engines with push rod oiling are: 1965-69 all, 1964 421 H.O., and all 389 Tri-Power engines, all 1963 421 H.O. engines. On these engines, rocker arm studs can now be replaced without removing the cylinder head. This is accomplished by the use of a new .005" oversize stud and a new reamer (J-22126), which is available from the Service Tool Division of Kent-Moore Organization, Inc., 28635 Mound Road, Warren, Michigan 48092.

1. Disconnect battery cable and drain radiator.
2. Pack oily rags around stud and over engine openings before removing stud.
3. After removing stud as outlined for earlier models, carefully ream stud hole, using the new reamer. This reamer is made with a removable pilot shaft. Stud hole must first be reamed with pilot shaft attached to reamer. Pilot shaft should then be removed and stud hole must be reamed again.
4. Clean stud hole and surrounding area. *If reamer did not clean up completely, it will be necessary to replace cylinder head.*
5. Remove intake manifold and valley cover.
6. Position rocker arm on new .005" stud and place rocker arm installer J-8927 on stud in place of rocker arm ball, Fig. 1.
7. Coat rocker arm stud with white lead and oil and drive stud into cylinder head about half way ($\frac{7}{16}$").
8. Clamp straight-edge on cylinder head as shown in Fig. 1, and position valve train gauge J-8928 in push rod hole so that it seats properly in rocker arm. *When working on right cylinder head, heater hose connector will have to be removed before straight-edge can be positioned correctly.*
9. With valve seated, drive rocker arm stud into cylinder head until the result outlined in Fig. 1 is obtained.
10. Remove tools and rocker arm. Then install push rod, rocker arm, ball, and tighten rocker arm ball retaining nut. Finally, install parts removed and fill radiator.

Fig. 2 Slots filled in rocker arm stud

Fig. 3 Tools positioned to remove rocker arm stud

1963-64 V8s Engines Without Push Rod Oiling

On these engines, the new .005" oversize stud that is available for engines with push rod oiling (see above) as well as the new reamer must also be used but the cylinder head must be removed to clean the metal particles out of the oil gallery. Therefore, follow the procedure given above as it applies.

4-195

NOTE: Rocker arm studs are replaceable provided a press of two tons capacity or more is available. Both standard and .003" oversize studs are available. If replacing a stud that has become loose, use a .003" oversize stud. If replacing a stud that is broken or has faulty threads, use a standard size stud.

1. Remove cylinder head.
2. With rocker arm removed, file two slots $\frac{3}{32}$" to $\frac{1}{8}$" deep on opposite sides of stud, Fig. 2. Top of slots should be $\frac{1}{4}$" to $\frac{3}{8}$" below thread travel.
3. Place washer at bottom of stud.
4. Place stud remover on stud, Fig. 3.
5. Thread standard nut on stud remover and turn nut until stud is out of head.
6. Position rocker arm on new stud and place Installer Tool, Fig. 7, on stud in place of rocker arm ball.
7. Coat stud with white lead and oil

Fig. 7 Pressing in new rocker arm stud. 4-195

Fig. 8 Position of gauge when stud is properly installed. 4-195

with cylinder head mounted on press on tool so studs are vertical as shown.

8. Press stud into head until it is in about half way ($\frac{7}{16}$").
9. Clamp straight edge on cylinder head as shown in Fig. 7 and position Valve Train Gauge in push rod hole so that it seats properly in rocker arm.
10. With valve seated, slowly press stud into cylinder head until gauge projects about midway between end of gauge and step with respect to straight edge as shown in Fig. 8.
11. Remove stud installer, rocker arm ball and straight edge.
12. Install rocker arm and ball and install nut loosely.
13. Replace cylinder head.

When the valve rocker arm ball retaining nut is tightened to a torque of 15-25 ft. lbs., proper location of the rocker arm with respect to the push rod and valve lifter is automatically assured.

NOTE

In the event that the nut can be turned down to the point where the required 15-25 ft. lbs. of torque cannot be obtained, probably the stud has worked itself up out of position. If such is the case, run the nut all the way up flush with the top of the stud threads and hammer the stud down with a brass drift to get the threads nearer to the cylinder head casting, which should permit the proper torque to be obtained.

Fig. 9 Hydraulic valve lifter. Some lifters do not have the ball check valve spring shown

VALVE GUIDES

Valve guides are cast integral with the cylinder head. Valves with oversize stems are available in .001", .003" and .005" larger than standard.

Oversize reamers are required to enlarge valve guide holes to fit the oversize stems. For best results when installing .005" oversize valve stem use a .003" oversize reamer first and then ream to .005" oversize. Always reface the valve and valve seat after reaming valve guide. Valves are marked .001, .003 or .005 with colored ink.

VALVE LIFTERS

Remove intake manifold, push rod cover and rocker arm cover. Loosen rocker arm ball nut and move rocker arm off push rod. Remove push rod.

Remove lifter or lifters. If more than one lifter is to be replaced, be sure to identify them (push rods as well) so they will be installed in the same position, Fig. 9.

TIMING COVER

NOTE: If necessary to replace the cover oil seal on 1963 V8-326 and all 1964-69, it can be accomplished without removing the timing chain cover.

4-195 Engine

1. To remove cover, drain radiator.
2. Remove generator, fuel pump and vibration damper.
3. Remove water hose at cover.
4. Remove cover attaching bolts.
5. Loosen cover-to-intake manifold draw bolt and remove cover.
6. Reverse foregoing procedure to install cover and torque oil pan-to-cover screws to 15 ft. lbs.

1963-69 V8s

1. Drain cooling system.
2. Loosen alternator adjusting bolts.
3. Remove fan and accessory drive belts.

Fig. 12 Front of engine with timing case cover removed. V8 engines.

Fig. 13 Front of engine with cover removed. 4-195 engine

Fig. 14 Valve timing marks. 4-195 and V8 engines

4. Remove fan and pulley.
5. Disconnect radiator hoses.
6. Remove fuel pump.
7. Remove vibration damper.
8. Remove front four oil pan-to-timing chain cover screws, Fig. 12.
9. Remove cover attaching screws.
10. Pull cover forward to clear studs and remove.

TIMING CHAIN

4-195 Engine

1. To remove, take off cover, fuel pump eccentric and crankshaft oil seal.
2. Remove chain tensioner spring and bumper, Fig. 13. *Right hand bumper must be removed before spring is removed because of hook in end of spring. Do not attempt to remove spring by stretching or twisting as spring may be damaged.*
3. Align timing marks on sprockets to simplify proper positioning on reassembly, Fig. 14.
4. Slide chain and sprockets off shafts.
5. Install new chain and/or sprockets, making sure marks on sprockets are aligned exactly on a straight line passing through shaft centers. Camshaft should extend through sprocket so that hole in fuel pump eccentric will locate on shaft.
6. If tensioner bumpers are worn excessively, replace them. Install chain tensioner assembly, crankshaft oil seal, fuel pump eccentric, bushing and cover.

V8 Engines

1. Remove timing chain cover, making certain O-ring seal and hollow dowels are retained for installation at assembly.
2. Remove fuel pump eccentric, bushing and timing chain cover oil seal, Fig. 12.
3. Align timing marks to simplify proper positioning of sprockets during assembly, Fig. 14.
4. Slide off chain and sprockets.
5. Install new chain and sprockets, making sure timing marks are aligned exactly on a straight line passing through the shaft centers, Fig. 14. Camshaft should extend through sprocket so that hole in fuel pump eccentric will locate on shaft.
6. Install fuel pump eccentric and bushing, indexing tab on eccentric with keyway cutout in sprocket. Install retainer bolt with washer and tighten securely.
7. Making sure hollow dowels are in place in block, place timing chain cover gasket over studs and dowels.
8. Install cover, making sure O-ring seal is in place.

CAMSHAFT

4-195 Engine

1. To remove, take off grille lower panel, grille and hood latch as an assembly.
2. Remove front bumper, radiator, intake manifold, timing cover, distributor, chain and sprockets, valve lifters and camshaft thrust plate.

3. Pull out camshaft using care not to damage bearings.
4. Reverse removal procedure to install, being sure to install camshaft thrust plate, indexing slot in plate with slot in block.

All V8s

The camshaft and camshaft bearings can be replaced with the engine installed in the car or with engine removed and disassembled for overhaul. However, to replace the rear camshaft bearing without removing and completely disassembling the engine, the propeller shaft, transmission and clutch housing must first be removed. The procedure for removing the camshaft is as follows:

1. Remove radiator, fan and pulleys.
2. On 1963-68 air conditioned cars, remove alternator and its mounting bracket.
3. Remove crankcase ventilator hose or outlet pipe.
4. Remove rocker arm covers.
5. Remove intake manifold. *Make certain "O" ring seal between intake manifold and timing chain cover is retained and installed during assembly.*
6. Remove push rod cover.
7. Loosen rocker arm ball retaining nuts so that rocker arms can be disengaged from push rods and turned sideways.
8. Remove push rods and hydraulic lifters, keeping them in proper sequence so that they may be returned to their original locations.
9. Remove vibration damper.
10. Remove fuel pump.
11. Remove timing chain cover.
12. Remove fuel pump eccentric and fuel pump bushing.
13. Remove chain and sprockets.
14. Remove camshaft thrust plate and carefully pull camshaft from engine. *Clearance for camshaft removal is very limited and, in cases where engine mounts are worn excessively, it may be necessary to raise the front of the engine to permit removal.*

PISTON & ROD, ASSEMBLE

Assemble pistons and rods as indicated in Figs. 21 and 22.

PISTONS, PINS & RINGS

Pistons are available in standard sizes and oversizes of .005, .010, .020 and .030″ on all four and six cylinder engines as well as 1963-69 V8s.

Piston rings are furnished in standard sizes only.

Piston pins are available in oversizes of .001 and .003″ on four cylinder engines and 1963-69 V8s. No oversizes are supplied on 6 cylinder engines.

MAIN & ROD BEARINGS

Main bearings are available in standard sizes and undersizes of .001 and .002″.

Fig. 21 Piston and rod assembly. 4-195

Fig. 22 Piston and rod assembly. 1963-68 V8s. (Oil spurt hole toward camshaft)

Fig. 25 Rear main bearing oil seal tool. V8-326

On 1965 V8-389 engine with three carburetors .001″ undersize is all that is available.

Rod bearings are available in standard sizes and undersizes of .001 and .002″. On 1963-66 V8-421 engines, undersizes of .0005″, .001 and .002″ are available.

CRANKSHAFT OIL SEAL

6-215 Engine

Remove engine from car then follow procedure as outlined in Chevrolet Chapter.

4-195 & V8-326

1. Remove oil pan and oil pump.
2. Remove rear main bearing cap.
3. Make a tool of brass bar stock to the dimensions shown in Fig. 25 to pack the upper seal as follows:
   a. Insert tool against one end of seal in cylinder block and drive seal gently into groove until tool bottoms.
   b. Remove tool and repeat at other end of seal in block.
4. Clean block and bearing cap parting line thoroughly.
5. Form a new seal in cap, Fig. 26.
6. Remove newly formed seal from cap and cut four pieces about ⅜″ long from this seal.
7. Work two ⅜″ pieces into each of gaps which have been made at end of seal in block. Without cutting off ends, work these seal pieces in until flush with parting line and no fibers are protruding over metal adjacent to groove.
8. Form another new seal in bearing cap.
9. Assemble cap to block and torque to specifications.
10. Remove cap and inspect parting line to be sure that no seal material has been compressed between block and cap. Clean as necessary.
11. Apply a $\frac{1}{16}$″ bead of sealer from center of seal across to external cork groove.
12. Install and torque bearing cap. Install oil pump and pan.

V8s Except 326

1. Remove oil pan, oil pump and pump drive shaft.
2. Remove oil baffle and cylinder block-to-oil baffle tube.
3. Remove rear main bearing cap.
4. Use tool shown in Fig. 27 made from brass bar stock to pack upper seal as follows:
   a. Insert tool against one end of oil seal in cylinder block and drive seal gently into groove until tool bottoms.
   b. Remove tool and repeat at other end of seal in cylinder block.
5. Clean block and bearing cap parting line thoroughly.
6. Form a new seal in cap.
7. Remove newly formed seal from cap and cut four pieces about ⅜″ long from this seal.
8. Work two ⅜″ pieces into each end of the gaps which have been made at the end of seal in cylinder block. Without cutting off the ends, work

Fig. 26 Installing rear main bearing oil seal. 4-195 and V8-326 engines

these seal pieces in until flush with parting line, being sure that no fibers are protruding over the metal adjacent to the groove.

9. Form another new seal in the cap.
10. Assemble the cap to the block and torque to specifications.
11. Remove cap and inspect parting line to insure that no seal material has been compressed between the block and cap.
12. Apply a $\frac{1}{16}$" bead of sealer from the center of the seal to the external cork groove.
13. Reassemble the cap and torque to specifications.

OIL PAN

4-195 Engine

1. To remove, drain oil and remove exhaust crossover pipe.
2. Support engine and remove front crossmember.
3. Remove flywheel housing front shield and lower cover.
4. Unfasten and remove oil pan.

6-215 Engine

1. Remove engine and transmission from car as a unit.
2. Remove oil pan, gaskets and end seals.
3. Install seal in rear main bearing cap, and front seal on timing gear cover, pressing tips in holes provided in cover.
4. Install side gaskets on cylinder block, using grease as a retainer. Side gasket tabs index into notches of front seal.
5. Install oil pan.

NOTE: Screws into timing gear cover should be installed last. They are installed at an angle and holes line up after rest of oil pan bolts are snugged up.

6. Install engine and transmission.

1963-69 Tempest V8 & 1967 Firebird V8

1. Remove engine, clutch and transmission from vehicle as a unit.
2. Remove clutch and transmission from engine.
3. Remove oil pan.
4. Install oil pan gaskets as shown in Figs. 28, 29, 30.
5. Install clutch and transmission to engine, and install the assembly into the vehicle.

1968-69 Firebird V8

1. Disconnect positive battery cable.
2. Disconnect fan shroud from radiator.
3. Remove air cleaner and distributor cap.
4. Make sure all hoses and wiring are free so as not to bind when engine is raised 4½" and moved forward 1½".
5. Raise car and drain crankcase.
6. Disconnect idler arm from frame.
7. Disconnect crossover pipe. If equipped with dual exhausts, disconnect exhaust pipes from manifolds.
8. Remove starter and flywheel cover.
9. Attach lifting tool J22603 to engine and place crossbar J22603-8 in position on tool.
10. Using frame jack or transmission jack, support engine at tool J22603 and remove motor mounts from engine.
11. Remove rear transmission to crossmember bolts.

Fig. 27 Rear main bearing seal tool dimensions. Make from brass bar stock. Pontiac V8s

12. Raise engine 4½" and at the same time move engine forward 1½".
13. Remove oil pan.

1966-69 Pontiac

1. Disconnect battery ground cable.
2. Remove fan shield.
3. On A/C cars, remove fan and pulley.
4. Disconnect engine ground cables.
5. On A/C cars, remove compressor from mounting brackets and position to one side.

NOTE: At this time, inspect all water hoses and wiring harnesses for proper routing to avoid excessive bind when engine is raised about 4½".

6. Raise car and drain crankcase.
7. Disconnect steering idler arm from frame.
8. Remove exhaust crossover pipe. If equipped with dual exhausts disconnect exhaust pipes from manifolds.
9. Remove starter and flywheel cover.
10. Remove front engine mount-to-frame bolts.

NOTE: On 1966 models, a special Engine

Fig. 28 Installing oil pan gasket retainers. V8-326 engine

Fig. 29 Front oil pan gasket overlapping side gaskets. V8-326 engine

Fig. 30 Rear oil pan gasket positioned in bearing cap. V8-326 engine

Fig. 31 Exploded view of oil pump. 4-195 and V8-326 engines

Support Bracket (J-22376) is available which is installed to tabs on timing cover with two $\frac{5}{16}$" bolts 1" long. With suitable equipment, support engine at this tool, remove left motor mount and loosen right engine mount-to-block bolts. Remove oil pan bolts, raise engine and remove pan.

On 1967-69 models, special Engine Lifting Tool (J-22603) is available. Bolt tool to timing chain cover with bolts provided with tool. Using frame jack or automatic transmission jack, support engine at Tool J-22603 and remove engine mounts. Loosen rear transmission mount. It may be necessary to remove this mount and rest rear of transmission on crossmember to obtain necessary clearance. Remove oil pan bolts and raise engine *straight up* until transmission is against floor pan. Remove pan by first rotating clockwise (facing forward) to clear oil pump.

NOTE: If work other than oil pan gasket replacement is to be performed, support engine with suitable blocks of wood and remove engine support.

1965 Pontiac

1. Remove engine and transmission.
2. Remove transmission (and clutch if used) from engine.
3. Remove oil pan.

1963-64 Pontiac

1. Drain radiator and oil pan.
2. Remove hood and air cleaner.
3. Disconnect battery ground cable.
4. Remove upper radiator support and fan guard.
5. Unfasten and move coil away from body.
6. Remove crossover and exhaust pipe-to-exhaust manifold retaining nuts.
7. Unfasten and lower idler arm and tie rod.
8. Remove front engine mount bolts.
9. Unfasten and lower starter motor.
10. Remove oil pan bolts.
11. Remove clutch housing lower cover.
12. Hook chain fall under front of intake manifold and lift engine as high as possible.
13. Let oil pan drop.
14. Remove front main bearing cap and move crankshaft to No. 1 "up" position.
15. Holding crossover pipe and tie rod down, remove oil pan.
16. Reverse removal procedure to install pan.

OIL PUMP

4-195 Engine

To remove pump, take off oil pan. Remove pump attaching screws and carefully lower pump away from block with one hand while removing pump drive shaft with the other hand.

When disassembling the pump, mark gears before removing them so they have the same relationship when they are reinstalled, Fig. 31. Clean and inspect all parts, discarding any that are worn or otherwise damaged.

To assemble, install drive and driven gear as marked before disassembly. Install cover and turn drive shaft by hand to insure that it turns freely and has a slight amount of end play. Torque cover bolts to 10-20 ft. lbs. Install pressure regular ball, spring and retainer, tightening retainer to 8-18 ft. lbs. *Do not attempt to change oil pressure by varying the length of the pressure regulator valve spring.* Install pump to engine and torque bolts to 20-35 ft. lbs.

V8-326 Engine

To remove the pump, remove the oil pan as outlined above. Then remove oil pump from engine.

In servicing the pump, refer to Fig. 31.

V8s Except 326

Remove oil pan. While holding pump in place, remove attaching screws. Lower the pump away from the block with one hand while removing the oil pump drive shaft with the other.

Remove oil screen and pressure regulator parts. Detach cover from pump body and take out gears, Fig. 33.

Examine all parts for damage and assemble. Do not attempt to change oil pressure by varying length of pressure regulator spring.

Position drive shaft in distributor and oil pump drive gear. Place pump in position in the block, indexing the drive shaft with pump drive gear shaft. Install attaching screws with lock washers and tighten securely.

Removal and installation of pump does not affect distributor timing since the oil pump and distributor drive gear are mounted on the distributor shaft.

WATER PUMP, REPLACE

V8s Except 326

Water pump is serviced only as an assembly. To remove, drain radiator and engine block. Remove fan belt, fan and pulley. Unfasten pump from block.

Install the pump in the reverse order. When pump is installed, drain hole will be at the bottom.

4-195 & V8-326 Engines

To remove water pump, which is *serviced only as an assembly,* drain cooling

Fig. 33 Oil pump disassembled. V8 Pontiac engines

system. Remove fan belt, fan and pulley. Unfasten and remove pump from engine.

When pump is installed on engine, drain hole will be at bottom. Tighten pump attaching nuts to 15 ft. lbs.

FUEL PUMP, REPLACE

1. Remove all gasket material from the pump and block gasket surfaces. Apply sealer on both sides of new gasket.
2. Position gasket on pump flange and hold pump in position against its mounting surface. Make sure rocker arm is riding on camshaft eccentric.
3. Press pump tight against its mounting. Install retaining screws and tighten them alternately.
4. Connect fuel lines. Then operate engine and check for leaks.

SERVICE NOTE: Before installing the pump, it is good practice to crank the engine so that the nose of the camshaft eccentric is out of the way of the fuel pump rocker arm when the pump is installed. In this way there will be the least amount of tension on the rocker arm, thereby easing the installation of the pump.

Overhead Camshaft Engine Section

INDEX OF SERVICE OPERATIONS

Accessory Drive Housing 2-528

Fig. 1 Adjusting timing belt with tension fixture shown

Fig. 2 Accessory drive housing mounting bolts

ENGINE, REPLACE

1. Disconnect cables at battery.
2. Drain cooling system.
3. Scribe alignment marks on hood around hood hinges and remove hood.
4. Disconnect engine wiring harness and engine ground straps.
5. Remove air cleaner and fan shield.
6. Disconnect all hoses at engine.
7. With manual transmission, remove radiator.
8. If equipped with power steering or air conditioning, remove pump and compressor from mounting brackets and set aside (do not disconnect hoses).
9. Remove engine fan and pulley.
10. Disconnect accelerator linkage.
11. Disconnect transmission vacuum modulator line and power brake vacuum line at carburetor and fold back out of the way.
12. Raise vehicle and drain crankcase.
13. Disconnect fuel lines at fuel pump, exhaust pipes from manifold and starter wires.
14. If equipped with automatic transmission, remove converter cover and 3 converter retaining bolts and slide converter to rear.
15. If equipped with manual transmission, disconnect clutch linkage and remove clutch shaft. Remove four lower bell housing bolts (two each side).
16. Disconnect transmission filler tube support and starter wire harness shield from cylinder head.
17. Remove two front engine mounts to-frame thru bolts.
18. Lower vehicle.
19. Support transmission with a jack and block of wood.
20. Remove two remaining bell housing bolts, raise transmission slightly and remove engine.
21. Reverse procedure to install. Do not lower engine completely while jack is supporting transmission.

TIMING BELT, ADJUST

1. Remove 3 screws on front of top cover. Lift up cover to disengage side clips. Remove retaining clips from cover.
2. Using the equipment shown in Fig. 1, set the pointer of the fixture on the zero mark. *This calibration must be performed prior to each use of the fixture to insure an accurate belt adjustment.*
3. Remove camshaft sprocket-to-camshaft bolt and install the fixture on the belt with the rollers on the outside (smooth) surface of belt. Thread the fixture mounting bolt into camshaft sprocket bolt location finger tight.
4. Squeeze indicator end (upper) of fixture and quickly release so that fixture assumes released or relaxed position.

Fig. 3 Valve timing marks

Fig. 4 Removing camshaft seal

Fig. 5 Seal and protector tool installed

5. With the tool installed as directed, adjust accessory drive housing, Fig. 2, up or down as required to obtain a tension adjuster indicator centered in the green range with drive housing mounting bolts torqued to 15 ft-lbs.
6. Remove tension fixture and install sprocket retaining bolt, making sure bolt threads and washer are free of dirt. Install cover.

CAMSHAFT SPROCKET OR SEAL

CAUTION: Do not use tools of any type, other than hands, to pry on timing belt during belt removal or replacement or during other service operations.

1. Remove timing belt top front cover. *For ease on reassembly, index three timing marks as shown in Fig. 3.*
2. Loosen accessory drive housing bolts, Fig. 2.
3. Remove belt from camshaft sprocket.
4. Remove sprocket.

NOTE: If necessary to replace camshaft seal, reinstall sprocket bolt. Thread a tool of the type shown, Fig. 4, into camshaft seal. Tighten center bolt on tool until seal is extracted. Install a suitable seal protector and pilot, Fig. 5, on end of camshaft. Slide seal over on tool, then drive it in place, Fig. 6.

5. Install sprocket, indexing pin on sprocket with hole in camshaft.
6. Install sprocket bolt finger tight.
7. Align timing marks and install belt.
8. Adjust timing and belt tension.
9. Torque sprocket bolt to 40 ft-lbs and install top cover.

ROCKER ARM COVER

1. Drain cooling system and disconnect radiator hose at fitting on cover.
2. Remove timing belt top cover.
3. Align timing marks and remove belt from camshaft sprocket.
4. Disconnect necessary fuel and vacuum lines.
5. Unfasten and remove rocker arm cover.
6. Reverse procedure to install.

CAMSHAFT

1. Remove camshaft sprocket and seal.
2. Remove rocker arm cover.
3. Using tools of the type shown in Fig. 7, drive camshaft from rocker cover. *Caution: Do not allow camshaft to damage bearing surfaces of rocker cover.*
4. Remove parts shown from rear of camshaft, Fig. 8.
5. Remove water outlet fitting and thermostat from rocker cover.
6. Clean all parts and inspect for wear or damage. Minor nicks or scratches on edge of bearing surface can be corrected with a suitable scraper or file.

Installation

1. Install camshaft into rocker cover.

Fig. 6 Installing camshaft seal

Fig. 7 Removing camshaft

Fig. 8 Camshaft and related parts

Fig. 9 Thrust washer installation

Fig. 10 Installing camshaft bore plug

Fig. 11 Rocker arm retainer and lash adjuster

Fig. 12 Hydraulic lash adjuster disassembled

Fig. 14 Depressing valve spring

2. Install thrust washer, Fig. 9.
3. Install retaining bolt and washer and torque to 40 ft-lbs.
4. Using a tool of the type shown in Fig. 10, drive plug in so it is fully seated.

IMPORTANT: A camshaft bore plug not fully seated could result in excessive camshaft end play which is .003" to .009" when read at the sprocket end with a dial indicator.

5. Replace water outlet fitting and thermostat.

ROCKER ARM OR VALVE LASH ADJUSTER

1. Remove rocker arm cover.
2. Remove rocker arm and hydraulic lash adjuster assembly and store so that each assembly can be installed in its original location.

NOTE: If a new lash adjuster is to be installed, it will be necessary to check the leak-down rate and prime the adjuster before installation.

3. Install retainer clip, Fig. 11.
4. Place each lash adjuster in its original location, and install rocker cover.

Lash Adjuster Service

NOTE: Because of the important part hydraulic lash adjusters play in the operation of the engine, and the close tolerances to which they are manufactured, proper handling and, above all, cleanliness, cannot be overstressed when servicing these parts.

New adjusters are serviced as individual units, packaged with a plastic coating. Leave the coating on until ready to check leak-down rate. It is necessary to remove the oil from the new adjusters prior to checking leak-down rate since special oil is in new adjusters. Fill adjusters with SAE 10 oil before checking leak-down rate. If leak-down test equipment is not available, the supplier should check lash adjusters for you.

Removing Stuck Lash Adjuster

After removing the rocker arm, fill the vent hole adjacent to the stuck lifter with engine oil. Using a length of $\frac{3}{16}$" diameter rod approximately 4" in length, insert it into the top of the vent hole and strike the end of the rod with a hammer. The hydraulic effect of the oil on the base of the lash adjuster will then break the adjuster free from the boss in the cylinder head. The use of pliers for this operation is not recommended since lifter damage will result.

VALVE SPRINGS & SEALS

Valve springs and seals can be replaced without removing the cylinder head if tools of the type shown in Fig. 14 are available.

1. Remove rocker arm cover.
2. Remove rocker arm of valve being serviced.
3. Remove spark plug from cylinder of

Fig. 15 Valves and related parts

Fig. 16 Lower front timing belt cover bolts

Fig. 17 Crankshaft sprocket

Fig. 18 Front crankcase with cover removed

Engine Oiling System. OHC Six

valves to be serviced and install an air hose with an adapter that will screw into the spark plug hole.

CAUTION: When applying compressed air into the spark plug hole to hold the valve up, be sure the piston is all the way down in the cylinder, otherwise the fan will turn.

4. Install the hook end of the tool into the oil feed hole in lash adjuster bore. Hold in place and install fork end of valve spring compressor as shown. Compress valve spring, remove valve cup locks. Then remove tool, valve spring, cup shield and valve stem seal.

CYLINDER HEAD

Removal

1. Drain cooling system and remove air cleaner.
2. Disconnect accelerator pedal cable at bellcrank on manifold and fuel and vacuum lines at carburetor.
3. Disconnect exhaust pipe at manifold flange, then remove manifold bolts and clamps. Remove manifolds and carburetor as an assembly.
4. Remove rocker arm cover.
5. Remove timing belt upper front cover mounting support bracket and rear lower cover.
6. Disconnect spark plug wires.
7. Remove rocker arms and hydraulic valve lash adjusters. *Store rocker arms and lash adjusters so they can be replaced in exactly the same location.*
8. Remove head bolts and lift off head.

Installation

When installing a new head, transfer all serviceable parts to new head using new seals on intake and exhaust valve stems and new manifold gaskets.

Head bolts are of two different lengths. When inserted in proper holes, all bolts will project an equal distance from head. Do not use sealer of any kind on threads.

Pontiac recommends no numerical sequence for tightening cylinder head bolts. Tighten them a little at a time, starting at the center bolts and working alternately from side to side outward to the end bolts.

VALVE SERVICE

Fig. 15 shows the valves and related parts.

Valves with oversize stems are available in .001", .003" and .005" larger than standard. The same valve stem-to-guide clearance listed in the *Valve Specifications* table applies for oversize stems.

Carefully ream the valve guide. For best results when installing a .005" oversize valve stem, use a .003" oversize reamer first, then ream the .005" oversize. Always reface the valve seat after reaming valve guide.

When installing valve springs, place the closed coil end toward the cylinder head.

CRANKCASE COVER SEAL

1. Remove upper timing cover.
2. Align timing marks, Fig. 3.
3. Remove fan and water pump pulley.
4. Remove vibration damper.
5. Remove timing belt lower cover, Fig. 16.
6. Loosen accessory drive mounting bolts to provide slack in timing belt, Fig. 2.
7. Remove timing belt.
8. Remove crankshaft timing belt flange and sprocket, Fig. 17.
9. Pry seal from front of crankcase.
10. Install new seal with lip of seal inward, using a suitable seal driver.
11. Reverse procedure to install, being sure to align the belt timing marks and adjust belt tension, Fig. 1.

FRONT CRANKCASE COVER

1. Remove crankshaft sprocket.
2. Remove 4 front oil pan-to-crankcase cover bolts.
3. Loosen remaining oil pan bolts as necessary to provide clearance be-

Fig. 19 Oil filter by-pass valve

Fig. 20 Removing eccentric and distributor drive gear retaining pin

Fig. 21 Removing bearing and seal

Fig. 22 Rear main bearing oil seal

Fig. 23 Removing rear main bearing cap

tween cover and pan. *It may be necessary to jar oil pan to gain necessary clearance.*
4. Remove 5 cover bolts.
5. Remove cover and gasket. Clean gasket surface, using care to see that gasket particles do not fall into oil pan.
6. Reverse procedure to install, Fig. 18.

ACCESSORY DRIVE HOUSING

Oil Pressure Regulator Valve

1. Remove cap, washer and spring from housing.
2. Using a magnet, remove valve from housing.
3. Reverse procedure to install.

Oil Pump

1. Remove pump cover and gasket.
2. Remove two gears.
3. Replace worn parts, install cover with new gasket and torque bolts to 20 ft-lbs.

Housing Assembly

1. Remove timing belt top cover.
2. Align timing marks, Fig. 3.
3. Loosen 6 housing-to-cylinder block bolts, Fig. 2.
4. Remove timing belt from camshaft sprocket and distributor drive.
5. Disconnect fuel lines from fuel pump.
6. Remove distributor cap, vacuum lines and wires from distributor.
7. Remove housing assembly.
8. Reverse procedure to install, using new housing gasket. Be sure to align timing marks and adjust timing belt tension.

Oil Filter By-Pass Valve

1. Remove housing assembly.
2. Remove valve retaining screw, Fig. 19.
3. Remove by-pass valve.
4. Reverse procedure to install.

Sprocket, Seal, Fuel Pump, Distributor Drive

1. Remove housing assembly.
2. Look for and write down location of sprocket timing mark and direction of distributor rotor, then remove distributor.
3. Remove drive gear retaining pin, Fig. 20. Position shaft to allow adequate clearance in housing body for pin removal.
4. Remove shaft and sprocket.
5. If necessary to replace bearing or seal use a slide hammer and tool of the type shown in Fig. 21 to remove seal or bearing and seal together.
6. Reverse procedure to install.

OIL PAN

1. Disconnect battery cable.
2. Remove air cleaner.
3. On air conditioned cars, remove compressor from mounting brackets and position to one side.
4. Inspect all water hose and wiring harness for proper routing to prevent excessive binding when engine is raised about 4½".

NOTE: Before raising vehicle prop hood open at least 6" to insure adequate clearance between timing belt cover and inner hood panel.

5. Remove starter and flywheel cover.
6. Reroute or disconnect any wiring between bellcrank and floor pan to insure against damage when bell housing contacts floor pan.
7. Loosen transmission insulator-to-crossmember bolts.
8. Remove right and left engine insulator-to-frame bracket thru bolts.
9. Rotate vibration damper until timing mark is at bottom so crankshaft counterweights will be in proper position for oil pan removal.
10. With suitable equipment, raise engine at front until insulators clear frame brackets.
11. Remove oil pan bolts.
12. Raise engine at front. Apply a rearward force on engine-transmission assembly until oil pan clears flywheel housing and remove pan.
13. Reverse procedure to install.

Rear Main Bearing Seal

The rear main bearing oil seal can be replaced (both halves) without removal of crankshaft. Always replace upper and lower seal as a unit, Fig. 22.

1. Remove oil pan.

Fig. 24 Piston and rod assembly

2. Use a slide hammer of the type shown in Fig. 23 to remove bearing cap.
3. Pry seal from groove and bearing cap side seals.
4. Clean crankshaft surface.
5. Place new side seals in position and place bearing cap in vise and compress seals into place.
6. Insert new seal well lubricated with engine oil in bearing cap groove. Gradually push with a hammer handle until seal is rolled into place.
7. To replace upper half of seal, use a small hammer and brass pin punch to tap one end of oil seal until it protrudes far enough to be removed with pliers. Push new seal into place.
8. Install bearing cap and oil pan.

PISTONS & CRANKSHAFT BEARINGS

Service on pistons, rings, pins, main and rod bearings are conventional.

Assemble pistons to rods as shown in Fig. 24.

Clutch & Standard Transmission Section

NOTE: 1969 linkage adjustment information is in this section. Repair procedures on both automatic and manual shift transmissions are covered elsewhere in this manual. Procedures for removing automatic transmissions as well as linkage adjustments on 1963-68 models are included in the automatic transmission chapters. See Chapter Index

CLUTCH PEDAL, ADJUST

1964-66 Tempest

1. Unhook linkage return spring.
2. With clutch pedal against stop, loosen lock nut enough to allow adjusting rod to be turned out of swivel (V8) or push rod (6-cyl.) and rearward against clutch fork until clutch release bearing contacts pressure plate fingers lightly.
3. Rotate adjustable rod into swivel or push rod 3½ turns and tighten lock nut.
4. Install return spring and check free pedal travel; it should be about 1".

1963 Tempest

1. Unhook linkage return spring.
2. Loosen trunnion lock nuts enough to allow the rod and fork to be moved rearward until release bearing contacts pressure plate fingers lightly.
3. Run rear nut up to trunnion.
4. Shorten rod 7 turns and secure both nuts. Reinstall spring. Pedal free play should be approximately 1".

1965-69 All Models

1. Remove anti-rattle spring.
2. Loosen swivel jam nut.
3. With clutch pedal against stop and lash removed at clutch, adjust for lash by rotating fork adjusting rod into swivel 3½ turns and tighten lock nut.

1963-64 Pontiac

1. On standard clutch only, remove anti-rattle spring.
2. Loosen trunnion lock nuts enough to allow rod and fork to be moved rearward until release bearing contacts clutch release fingers lightly.
3. Run the rear nut up to the trunnion.
4. Shorten the rod 7 turns and secure both nuts. There should be approximately 1" of free play at the pedal.

CLUTCH, REPLACE

1964-69 All & 1963 Pontiac

1. Disconnect battery-to-starter cable.
2. Remove transmission as outlined below.
3. Remove release bearing through rear opening in clutch housing.
4. Remove pedal return spring, starter, front flywheel housing shield and flywheel housing.
5. Mark clutch cover and flywheel to insure reassembly in the same position as balanced at the factory.
6. Loosen bolts holding clutch cover to flywheel a little at a time until all tension is relieved. Then remove clutch and driven disc.
7. Reverse removal procedure to install the clutch and adjust pedal free travel.

1963 Tempest

1. To remove clutch, disconnect stabilizer bar at body frame rail.
2. Disconnect exhaust pipe.
3. Disconnect front of torque tube from clutch housing. Support torque tube at front after dropping front of tube enough to permit access to clutch.
4. Disconnect clutch rod from fork.
5. Disconnect clutch link from clutch housing stud.
6. Remove clutch housing with components intact.
7. Mark relationship between clutch cover and flywheel to maintain original balance if same clutch is being installed.
8. Remove clutch assembly.
9. Install clutch by reversing removal procedure. Torque clutch cover bolts 25-35 ft. lbs.

Fig. 1 Gearshift lever and housing disassembled. 1963 Tempest

THREE SPEED MANUAL TRANS.

Transmission, Replace

1963-69 Except 1963 Tempest

1. Disconnect speedometer cable.
2. Disconnect shift rods from transmission.
3. Remove propeller shaft.
4. Support rear of engine and remove transmission mount.
5. Remove 4 crossmember bolts and slide member rearward.
6. Remove 2 upper transmission-to-flywheel housing bolts, insert guide pins.
7. Remove two lower bolts.
8. Remove transmission.
9. Reverse procedure to install.

1963 Tempest

1. Raise car and support on underbody side rails.
2. Drain transmission and rear end, remove rear wheels and brake drums disconnect and remove rear axles from carrier assembly.
3. Disconnect speedometer cable and transmission controls.
4. Support torque tube and trans-axle separately and remove axle support bolts.
5. Disconnect rear tail pipe hanger. Disconnect rear lower control arms from differential housing.
6. Lower trans-axle slightly and remove crossmember. Separate trans-axle from torque tube and lower trans-axle.

Fig. 2 Four speed manual shift transmission gearshift linkage adjustments. 1963-64 Pontiac

SHIFT LINKAGE 3 SPEED TRANS.

1963 Pontiac, 1964-69 All

Column Shift

1. Align upper and lower gearshift levers on steering column in neutral position. Where provision has been made, insert a $\frac{3}{16}$" gauge pin through holes in levers.
2. Loosen clamp screws at transmission control rods.
3. Position levers on transmission in neutral.
4. Tighten clamp screws to 20 ft-lbs.

Floor Shift

1. Position selector lever in neutral.
2. Loosen trunnion jam nuts on transmission control rods.
3. Place transmission lever and bracket assembly in neutral. Where provision has been made, install a ¼" gauge pin through holes in bracket.
4. Position transmission levers in neutral.
5. Tighten jam nuts to 30 ft-lbs.
6. Remove gauge pin.

1963 Tempest

Remove & Replace

1. To remove the control, slide boot toward transmission and remove clevis pin and retaining ring from torque tube.
2. Remove ball from control tower.
3. Unfasten gearshift lever and housing from torque tube, Fig. 1.
4. Move shift lever and housing assembly toward front of car, removing control rod from manual shift shaft.
5. Remove boot from transmission.
6. Reverse removal procedure to install.

4 SP. TRANS. REPLACE

1963-69

Follow procedure outlined for 1963-69 three-speed models.

SHIFT LINKAGE 4 SPEED TRANS.

Except 1963-64 Pontiac

1. Place selector lever in neutral.
2. Loosen trunnion nuts on transmission control rods.
3. Place transmission lever and bracket assembly in neutral and install a gauge pin through holes and slot provided in bracket.
4. Position levers on transmission in neutral.
5. Tighten trunnion nuts and remove gauge pin.

1963-64 Pontiac

As shown in Fig. 2, a simple gauge block, locally made to the specifications indicated, will aid in making the proper adjustments. The adjustments can be made without the gauge block by having an assistant hold the manual shift lever in neutral position.

1. Remove gearshift lever seal from floor pan.
2. Place transmission in neutral and, if gauge block is used, position in slot.
3. Remove clevis pin at each shift lever.
4. On each shift rod, adjust threaded clevis to permit free entry of pin into hole in transmission shift lever.
5. Connect clevises to levers.
6. Remove gauge block and check shifts. If any roughness exists, one of the clevises may require adjustment of about ½ turn. Determine the rod and clevis requiring adjustment by sighting along the slot where the gauge block was used. *If transmission is removed from car, shift linkage should be adjusted before transmission is reinstalled.*

1969 AUTO. TRANS. LINKAGE, ADJUST

Adjustment procedures for the 1969 linkages are essentially the same as those for the 1968 units which are outlined in the front of this manual with the exception that the 1969 column shift linkage is adjusted in the "Park" position and the 1969 console shift linkage is adjusted in "Neutral". In addition, 1969 models incorporate a "back drive" linkage which must be adjusted to insure that the ignition can be locked with the transmission in "Park" before the shift linkage is adjusted.

Rear Axle, Propeller Shaft & Brake Section

TEMPEST

1963 REAR AXLE

Description

The differential and carrier assembly is a component of the transmission and differential assembly, Fig. 1. This design combines the two and is commonly referred to as a transaxle. The differential and carrier design utilizes a hypoid ring and drive pinion set with the pinion shaft above the center of the ring gear. The remaining components of the unit are conventional. The assembly is mounted on the rear suspension crossmember and is sprung with the body weight.

Each axle shaft is independently suspended and is free to move in a vertical plane in an arc. The axle shaft is attached to universal joints which in turn are splined into the differential side gears. The driving force is transmitted by the lower control arm and lateral forces are absorbed by self-aligning wheel bearings and rubber bushings at the lower control arm attachment to the rear crossmember.

The differential and carrier assembly used with both the manual shift and automatic transmissions are identical except for the drive pinion shaft, front pinion bearing adjustment nut, rear pinion bearing retainer, and oil seals.

The manual shift transmission drive pinion shaft is hollow and is splined internally to receive the transmission mainshaft. The drive pinion shaft used with the automatic transmission is also hollow but is splined externally so that the drive pinion shaft may be inserted in the transmission planet carrier hub. With automatic transmission, the turbine shaft passes through the drive pinion shaft to connect the turbine to the transmission. Details of the propeller shaft and torque tube are shown in Fig. 2.

Fig. 1 Differential and carrier assembly. 1963 Tempest

Fig. 2 Tempest propeller shaft and torque tube. 1963

Axle Shaft

1. Remove wheel and brake drum.
2. Through hole in axle shaft flange, remove four nuts securing axle bearing retainer to brake backing plate.
3. Pull brake backing plate outward slightly, then push it back on the control arm studs to break backing plate away from bearing retainer.
4. Remove four nuts and lock tabs from U-bolts attaching universal to axle flange.
5. Pull axle shaft outward enough to separate flange from U-bolts.
6. Remove flange from shaft.
7. Remove axle shaft from lower control arm. Replace bearing if necessary.

Installation

1. Insert shaft through lower control arm. Install flange on axle shaft splines. It may be necessary to tap flange onto splines if original parts are being installed.
2. Attach universal to flange on axle shaft. *Tighten U-bolts to 14-20 ft. lbs. Also be sure universal joint snap rings are properly installed.*
3. With bearing retainer and brake backing plate holes aligned with control arm studs, insert universal splined yoke through seal at side bearing and index with splines of side gears. Coat lip of seal and splines with hypoid oil to help prevent damage to seal from splines of universal yoke.
4. Secure bearing retainer to backing plate and torque nuts to 30-45 ft. lbs.
5. Install brake drum and wheel.

Fig. 3 Differential and carrier components 1963 Tempest. When used with four speed manual shift transmission a four-pinion differential is used

Prop. Shaft & Torque Tube

Manual Shift Trans.

1. Remove parking brake cable from torque tube.
2. Disconnect exhaust system at engine and slide off entire system.
3. Remove gearshift housing.
4. Remove flywheel housing lower cover.
5. Remove torque tube access hole cover.
6. Remove propeller shaft flange bolts.
7. Place a short piece of rubber hose or rag between propeller shaft and torque tube.
8. Unfasten torque tube from flywheel housing.
9. Pry torque tube and propeller shaft away and down from flywheel housing.
10. Place block of wood 2″ square between transmission extension and floor of car to position transmission for reassembly. Support torque tube with stand.
11. Unfasten torque tube from transmission. Remove propeller shaft and torque tube as a unit by pulling on propeller shaft flange.

Installation Notes

Reverse removal procedure to install, being sure to observe the following:

Assemble propeller shaft in torque tube and place a short piece of rubber hose or rag between front of propeller shaft and torque tube *so that coating on propeller shaft will not be damaged.*

When installing shaft in torque tube, the shaft should enter without using force. Extreme care should be exercised not to damage the coating on propeller shaft as damage to this coating will shorten the life of the drive line.

Coat spline generously with axle lube and use care when entering shaft into extension seal. Never allow weight of shaft to rest on seal.

When installing shaft into transmission, be sure to engage spline of shaft into transmission and journal diameter into transmission extension bearings so as not to damage journal surface. Visual check of propeller shaft alignment into transmission extension is required, and if absolutely necessary, tap front flange lightly with a soft rubber hammer. Be sure splines are completely engaged in transmission.

Tighten torque tube to transmission extension bolts to 30-45 ft. lbs. torque. Torque bolts securing propeller shaft flange to clutch drive shaft to 30-45 ft. lbs.

Automatic Transmission

1. Remove parking brake cable and vacuum line from torque tube.
2. Remove stabilizer bar.
3. Disconnect at engine and slide entire exhaust system off.
4. Remove flywheel housing lower cover.
5. Disconnect propeller shaft flange from flywheel.
6. Loosen half way the bolts that connect torque tube to flywheel housing.
7. Place a short piece of rubber hose or rag between propeller shaft and torque tube to prevent damage to coating on drive line.
8. Using a screwdriver, pry propeller shaft flange to rear far enough for pilot to clear recess in flywheel.
9. Disconnect torque tube from flywheel housing.
10. Pull shaft and torque tube down and away from flywheel housing.
11. Place a 2″ square block of wood between transmission and floor of car to position transmission extension for reassembly.
12. Support torque tube and unfasten it from transmission. Remove propeller shaft and torque tube as a unit by pulling on propeller shaft flange.
13. Pull propeller shaft out of torque tube, do so without using force. Use extreme care not to damage coating on propeller shaft as damage to this coating will shorten the life of the drive line.

Installation Notes

Reverse removal procedure to install the propeller shaft and torque tube, observing the precautions outlined for cars with manual shift transmission.

TEMPEST TRANSAXLE, REPLACE

1963

1. Raise car so that rear wheels hang free. Support torque tube and transaxle separately. Drain lube from transaxle.
2. Remove rear wheels and brake drums.
3. Remove bolts securing axle shaft bearing retainer to brake backing plate. Pull axle shafts out far enough to remove U-joint flanges from differential carrier.
4. On manual transmission jobs, disconnect speedometer cable and parking brake spring from differential carrier. On automatic transmission cars, disconnect vacuum line, parking brake return spring, T.V. rod, transmission control cable and speedometer cable. Remove oil filler tube.
5. Disconnect torque tube from transmission extension.
6. Unfasten differential carrier from rear crossmember. Remove bolt from bracket.
7. On manual transmission cars, remove muffler support bracket from torque tube.
8. Separate transaxle from torque tube and lower transaxle from car.
9. To install, reverse removal procedure.

TEMPEST DIFF. CARRIER, 1963

1. Separate differential and transmission, Fig. 3.
2. On A.T. jobs, pull off governor drive gear and spacers.
3. Remove differential side bearing oil seals (if the occasion arises, these seals may be replaced without taking assembly for car).
4. Remove side cover and lift out differential case and ring gear.
5. Remove pinion rear bearing retainer and shim pack. On A.T. jobs only, remove rubber oil passage seal. Tap retainer out from front of case if necessary.
6. Remove front pinion bearing adjusting nut lock and nut.
7. Remove drive pinion.
8. Remove side bearing adjusting nut lock screw and nut.
9. Remove side bearing race. If difficult to remove, screw in adjusting nut until race is pushed out into carrier housing. Remove adjusting nut.
10. Remove adjusting nut lock screw, nut, bearing race and O-ring seal from side cover.

Diff. Case and Ring Gear

1. If side bearings or case is to be replaced, remove bearings.
2. A mark is scribed across parting line of case and cover to aid in alignment on reassembly.

Fig. 4 Determining drive pinion shim thickness required

+2	SUBTRACT .002 FROM SHIM STACK
+3	SUBTRACT .003 FROM SHIM STACK
+4	SUBTRACT .004 FROM SHIM STACK

Fig. 6 Drive pinion correction chart

3. Remove 8 ring gear bolts.
4. Reinstall two bolts partially in ring gear and tap ring gear off case.
5. Separate cover and case. Remove side gear and thrust washer from cover half. Drive out roll pin which retains cross shaft and drive out cross shaft.
6. Remove pinions, thrust washers and side gear from case.
7. Reassemble in reverse order and tighten ring gear bolts to 55-65 ft. lbs.

Drive Pinion

1. On A.T. jobs, remove oil ring from pinion shaft.
2. Remove front pinion bearing.
3. Press off speedometer gear.
4. Press off rear bearing.
5. Place rear pinion bearing in its retainer. Place tool (J-8919) on retainer as shown, Fig. 4. Use feeler gauge as shown to determine correct shim thickness required on reassembly. Use chart, Fig. 5, to convert feeler gauge readings to shim specifications. If pinion shaft is marked, use chart, Fig. 6, for correction. *If bearing race is to be replaced, do so before determining shim requirements.*
6. Press on rear bearing, speedometer drive gear and front bearing. On A.T. jobs, replace oil ring.

Assemble and Adjust Differential and Carrier

1. Install side bearing race in carrier casting.
2. Start side bearing adjusting nut.
3. Position side bearing race in side cover and start side bearing adjusting nut.
4. Position ring gear and differential case in carrier.
5. With oil seal removed, place side cover on case with four bolts. Be sure two aligning bolts are in correct holes.
6. Turn side bearing nut in cover finger tight.
7. Install tool, Fig. 7, in end of differential cross shaft through side cover.
8. Adjust side bearing preload to 10-20 inch lbs. by turning adjusting nut in carrier. Check preload as shown.
9. Install adjusting nut lock screws and washers.
10. Remove tool, Fig. 7, from shaft and remove side cover from carrier, and case and ring gear from carrier housing.
11. Install shim pack as already determined. Install new rubber oil passage seal (A.T. only). Install new O-ring seal on rear pinion bearing retainer. Install retainer on housing (8 bolts).
12. Invert carrier and position pinion shaft in carrier. Install pinion adjusting nut (also O-ring seal on A.T. jobs). Tighten nut until play of pinion shaft is eliminated.
13. Install tool, Fig. 8, inside pinion shaft and tighten nut.
14. Adjust pinion bearing preload to 10-16 inch lbs., Fig. 9.
15. Place ring gear and differential in carrier. Install side cover without

Fig. 7 Checking side bearing preload

Fig. 8 Tool installed in pinion shaft

Fig. 9 Adjusting pinion bearing preload

O-ring seal and retain with four bolts. Remove side bearing adjusting nut lock screws.

16. Install tools as shown in Fig. 10. Dial indicator should rest squarely on line scribed on handle of J-8903.
17. Insert large screwdriver in other end of differential shaft.
18. Adjust ring gear and pinion backlash to .004-.009″ by loosening one adjusting nut and tightening the other one notch at a time (do not rotate pinion). Move ring gear toward pinion to decrease backlash and away from pinion to increase backlash. Remove tools except J-8903.
19. Reinstall side bearing adjusting nut lock screws (10-20 inch lbs. torque).
20. Rotate pinion shaft clockwise 4 turns and counterclockwise 4 turns while creating a drag on tool J-8903, Fig. 10.
21. Remove side cover and ring gear.
22. Analyze tooth patterns and make necessary corrections. *Any change in shim pack will require new pinion bearing preload and side bearing backlash adjustments.* If no corrections are necessary proceed with reassembly.
23. Reinstall ring gear and differential. Install side cover, using new O-ring seal. Tighten side cover bolts to 10-20 ft. lbs. Apply bead of sealer and install new side bearing oil seals. Install drain and filler plugs.
24. Install governor drive gear and spacers on A.T. jobs as outlined in Transmission Section.
25. Assemble transmission and differential carrier.

REAR AXLES

Figs. 11 and 12 illustrate the rear axle assemblies used on 1964-69 conventional models. When necessary to overhaul either of these units, refer to the *Rear Axle Specifications* table in this chapter.

1964 Tempest & All 1965-69

In this rear axle, Fig. 11, the rear axle housing and differential carrier are cast into an integral assembly. The drive pinion assembly is mounted in two opposed tapered roller bearings. The pinion bearings are preloaded by a spacer behind the front bearing. The pinion is positioned by a washer between the head of the pinion and the rear bearing.

The differential is supported in the carrier by two tapered roller side bearings. These bearings are preloaded by shims located between the bearings and carrier housing. The differential assembly is positioned for proper ring gear and pinion backlash by varying these shims. The differential case houses two side gears in mesh with two pinions mounted on a pinion shaft which is held in place by a lock screw. The side gears and pinions are backed by thrust washers.

1963-64 Pontiac

In these rear axles, Fig. 12, the drive pinion is mounted in two tapered roller bearings that are preloaded by a collapsible spacer. The pinion is positioned by shims located between the head of the pinion and the rear pinion bearing. The differential is supported in the carrier by two tapered roller side bearings. These bearings are preloaded by two threaded sleeves or ring nuts between the bearings and pedestals. The differential assembly is positioned for proper ring gear and pinion backlash by varying the adjustment of these ring nuts. The differential case houses two side gears in mesh with two pinions mounted on a pinion shaft which is held in place by a lock screw. The side gears and pinions are backed by thrust washers.

Fig. 10 Tools in position for adjusting backlash

Diff. Carrier Assy

1964 Tempest & All 1965-69

Construction of the axle assembly is such that service operations may be performed with the housing installed in the vehicle or with the housing removed and installed in a holding fixture. The following procedure is necessary only when the housing requires replacement.

1. Raise car and place a floor jack under center of axle housing so it starts to raise rear axle assembly. Place car stands solidly under body members on both sides.
2. Disconnect rear U-joint from drive pinion flange and support propeller shaft out of the way.
3. Remove both axle shafts.
4. Support both brake backing plates out of the way.
5. Disconnect rear brake hose bracket by removing top cover bolt. Remove brake line from housing by bending back tabs.
6. Loosen remaining cover bolts, break loose cover about ⅛″ and allow lube to drain.
7. Disconnect shock absorbers at axle housing. Lower jack under housing until rear springs can be removed.
8. Disconnect upper control arms at axle housing.
9. Disconnect lower control arms at axle housing and remove rear axle assembly from vehicle.
10. Reverse removal procedure to install the unit.

1963-64 Pontiac

In servicing these rear axles, it is not necessary to remove the rear axle assembly for any normal repairs. The axle shafts and carrier assembly can easily be removed from the vehicle, leaving the axle housing in place.

1. Remove axle shafts and drive shaft as explained below.
2. Drain oil by loosening all differential attaching nuts and then pulling carrier out about ⅛″.

Fig. 11 Rear axle assembly exploded. 1964 Tempest and all 1965-69

Fig. 12 Rear axle assembly, 1963-64 Pontiac

3. Allow oil to drain thoroughly, then remove attaching nuts and remove carrier assembly from housing.

Axle Shaft, Replace

1964 Tempest & All 1965-69

NOTE: Design allows for axle shaft end play up to .032″ loose. This end play can be checked with the wheel and brake drum removed by measuring the difference between the end of the housing and the axle shaft flange while moving the axle shaft in and out by hand. End play over .032″ is excessive. Compensating for all of the end play by inserting a shim inboard of the bearing in the housing is not recommended since it ignores the end play of the bearing itself, and may result in improper seating of the gasket or backing plate against the housing. If the end play is excessive, the axle shaft and bearing assembly should be removed and the cause of the excessive end play corrected.

1. To remove, take off wheels and brake drums.
2. Remove nuts holding retainer plates and brake backing plates. Pull retainers clear of bolts and reinstall two lower nuts finger tight to hold backing plate in position.

Fig. 13 Removing axle shaft with slide hammer-type propeller

3. Use a slide hammer-type puller to remove axle shaft.

Axle Shaft Bearing

1. Press axle shaft bearing off shaft.
2. Press new bearing against shoulder on shaft.

CAUTION: Outer retainer plate which retains bearing in housing must be on axle shaft before bearing is installed. A new outer retainer gasket can be installed after bearing. Use care not to wedge outer retainer between bearing and shoulder of shaft. Do not press bearing and inner retainer on in one operation.

3. Press new inner retainer ring against bearing.

Axle Shaft Seal

1. Insert suitable tongs behind seal and pull straight out to remove seal.
2. Apply sealer to outside diameter of new seal.
3. Position seal over a suitable installer and drive straight into axle housing until tool bottoms on bearing shoulder in housing.

Axle Shaft, Install

1. Apply a coat of wheel bearing grease in bearing recess of housing. Also lightly lubricate the axle shaft with rear axle lube from the sealing surface to about 6″ inboard.
2. Install *new* axle housing-to-brake backing plate gasket.
3. Install brake assembly with backing plate in proper position.
4. With a *new* outer retainer gasket in proper position, insert axle shaft until splines engage differential. *Do not allow shaft to drag on seal.*
5. Drive axle shaft into position.
6. Place new outer retainer gasket and retainer over studs and install nuts, torqueing them to 45-55 ft-lbs.
7. Install brake drums and wheels.

1963-64 Pontiac

1. Remove wheel. Wheel nuts on left side of car have left-hand threads.
2. Remove brake drum.
3. Remove brake backing plate from axle housing (4 bolts).
4. Remove axle shaft. If bearing is a tight fit in housing, use a slide hammer-type puller, Fig. 13. Do not dislodge brake backing plate or brake pipe may be damaged.

NOTE: While pulling axle shaft out through seal, support shaft carefully in center of seal to avoid cutting seal lip. If seal is to be removed, use a hook-type puller to remove it from axle housing. Apply oil to seal lip and coat outside of seal retainer in axle housing with a suitable sealer. Be sure that sealer does not get smeared on seal lip. The surface of axle shaft that contacts seal must be smooth; if nicked or burred, smooth carefully with very fine emery cloth.

Installation

1. Place bearing retainer gasket over bearing on axle shaft.
2. Install axle shaft, being sure not to allow shaft to rest on or drag on lip of seal.
3. Position bearing outer retainer and gasket and tighten bearing retainer nuts 30 to 45 ft. lbs.
4. Install brake drums and wheels.

Axle Shaft Bearing

1. Press axle shaft out of bearing.
2. If removed, install bearing outer retainer on shaft. Then install bearing on shaft firmly against shoulder on shaft, Fig. 14.
3. Press a new bearing inner retainer ring firmly against bearing. *Do not press bearing and retainer on in one operation because edge of radius of retainer will climb over corner of bearing inner race and force grease seals into bearing balls.*
4. Install axle shafts as outlined above.

Fig. 14 Installing bearing on axle shaft, 1963-64 Pontiac

Fig. 15 Insulated propeller shaft. 1964-68 (typical)

PROPELLER SHAFT

1964-69

Two designs of propeller shafts are used, a solid type which is of one piece tubular steel construction, and a "rubber" type which incorporates rubber torsional dampers between two concentric tubes of steel.

Two methods are used to retain the U-joint bearings to the yoke: conventional snap rings are used at the companion flange of the differential: the remaining six U-joint bearings are held in place with nylon rings.

SERVICE NOTE: Because of the elastic properties of the nylon retainers, Fig. 15, it is not possible to drive the bearings out in the conventional manner. They must be pressed out, which shears the nylon retainers in half, rendering the bearings and journal unsuitable for further use. Therefore, when reassembling, a new bearing and journal assembly employing the conventional snap ring retainers must be used.

CAUTION: Do not attempt to replace the U-joints of propeller shafts from cars equipped with 421 H.O. engines and axles of 3.42 ratio and over. They are high speed balanced assemblies and replacement of composite U-joint will destroy this balance.

1963 Pontiac

1. Remove U-bolt nuts, lock plates and U-bolts from drive pinion flange.
2. Use a suitable rubber band to hold bearings onto U-joint spider or cross (if tie wire has been removed) to prevent loss of needle bearings when rear U-joint is disconnected.
3. Remove complete drive line assembly by sliding rearward to disengage from splines of transmission shaft.
4. Before installing, inspect outer diameter of splined yoke for burrs. Remove any burrs with very fine emery cloth to prevent damage to transmission seal.
5. Apply engine oil to spline and outside diameter of yoke and slide propeller shaft front U-joint onto transmission shaft.
6. Position rear U-joint to pinion flange, making sure trunnion bearings are properly aligned in flange yoke.
7. Install U-bolts and tighten 14 to 20 ft. lbs. Bend ears of lock plates against flat side of nuts.

BRAKE ADJUSTMENTS

1963-69 Self-Adjusting Brakes

These brakes, Fig. 16, have self-adjusting shoe mechanisms that assure correct lining-to-drum clearances at all times. The automatic adjusters operate only when the brakes are applied as the car is moving rearward or when the car comes to an uphill stop.

Although the brakes are self-adjusting, an initial adjustment is necessary after the brake shoes have been relined or replaced, or when the length of the star wheel adjuster has been changed during some other service operation.

Frequent usage of an automatic transmission forward range to halt reverse vehicle motion may prevent the automatic adjusters from functioning, thereby inducing low pedal heights. Should low pedal heights be encounterd, it is recommended that numerous forward and reverse stops be made until satisfactory pedal height is obtained.

If a low pedal height condition cannot be corrected by making numerous reverse stops (provided the hydraulic system is free of air) it indicates that the self-adjusting mechanism is not functioning. Therefore, it will be necessary to remove the drum, clean, free up and lubricate the adjusting mechanism. Then adjust the brakes as follows, being sure the parking brake is fully released.

Adjustment

1. Remove adjusting hole cover from brake backing plate and, from backing plate side, turn adjusting screw upward with a screwdriver or other suitable tool to expand the shoes until a slight drag is felt when the drum is rotated.
2. Remove brake drum.
3. While holding adjusting lever out of engagement with the adjusting screw, Fig. 17, back off the adjusting screw one full turn with the fingers. *NOTE: If finger movement will not turn the screw, free it up. If this is not done, the adjusting lever will not turn the screw during subsequent vehicle operation. Lubricate the screw with oil and coat with wheel bearing grease. Any other*

Fig. 16 Right front and rear brake. 1963-69 (typical)

Fig. 17 Backing off adjusting screw. 1963-69

adjustment procedure may cause damage to the adjusting screw with consequent self-adjuster problems.

Anchor Pins, 1963-64 Pontiac

Whenever the brake shoes have been relined or replaced, it is necessary to adjust the anchor pins to insure full contact of the new linings with the brake drum. No attempt should be made to correct brake pull by changing the anchor pin setting once the linings have been seated. Adjustable anchor pins are used only on the front brakes. The adjustment procedure is as follows:

1. With wheels raised, remove adjusting hole cover from brake backing plate and expand the shoes by turning the adjusting screw until a heavy drag is felt when wheel is rotated.
2. Release adjusting screw one full turn.
3. Insert a screwdriver through adjusting hole in backing plate and force the adjusting screw toward the front (primary) shoe. Then turn the drum backward to force the lower end of the primary shoe against the drum.
4. Check clearance at anchor and adjusting screw ends of the secondary (rear) shoe with a .015" feeler gauge inserted in the brake drum slot. If these clearances are not equal within plus or minus .002", adjust anchor and adjusting screw as required. However, the clearance at the anchor end of the shoe should not be more than that at the adjusting screw end.
5. The exposed end of the adjustable anchor pins have a beveled face. The high side of the bevel designates the high side of the eccentric. Hold the anchor pin and tighten the lock as tightly as possible.

Service Note

The rear brakes on 1963-64 models have no slot in the brake drums for insertion of a feeler gauge for checking. Adjustment may be made, therefore, by lengthening the adjusting screw to create a heavy drag as the drum is rotated, then backing off 30 notches.

PARKING BRAKE, ADJUST

CAUTION: It is very important that parking brake cables are not adjusted too tightly causing brake drag. With automatic brake adjusters, a tight cable causes brake drag and also positions the secondary brake shoe, hence the adjuster lever, so that it continues to adjust to compensate for wear caused by the drag. The result is a cycle of wear and adjustment that can wear out linings very rapidly.

1966-69

1. Jack up both rear wheels.
2. Pull parking brake pedal five to seven notches from fully released position (two notches on Firebird models).
3. Loosen equalizer rear lock nut. Adjust forward nut until a light to moderate drag is felt when rear wheels are rotated.
4. Tighten lock nut. Fully release parking brake and rotate rear wheels to be sure there is no drag.

1965 Pontiac

1. Jack up both rear wheels.
2. Push parking brake pedal 3 notches from fully released position.
3. Loosen equalizer rear lock nut.
4. Adjust forward nut until a light drag is felt when rear wheels are rotated.
5. Tighten lock nut.
6. Fully release parking brake and check for free rotation of rear wheels.

1963-64 Pontiac

1. With service brakes properly adjusted, apply parking brake slightly and check equalization by turning rear wheels by hand.
2. If only a slight difference exists, loosen the adjusting screw of the tighter brakes. *NOTE—On self-adjusting brakes, it will be necessary to disengage the adjusting lever from the star wheel adjuster as shown in Fig. 17.*
3. If equalization requires more than a few notches movement, retighten the adjusting screw to the point for proper adjustment for that brake and equalize the rear cable by loosening the cable clamp screws at the equalizer clevis.
4. Pull downward on the tight side of the cable. It may be necessary to open the clamp with a screwdriver to allow the cable to equalize.
5. Tighten the clamp screws on the equalizer while the parking brake is still in applied position.
6. When parking brake is released, it should be possible to turn each wheel by hand without feeling drag when rear cable is pulled downward by the other hand, gripping cable midway between conduit and guide on frame.
7. Close adjustment for tension may be secure by adjusting the clevis at the rear end of the front cable. In adjusting here, be certain to turn clevis on or off cable end and do not twist the cable. Coarse adjustment is secured by selecting the correct hole in the equalizer.

1964-65 Tempest

1. Apply parking brake slightly and check equalization by turning rear wheels by hand. If only a slight difference exists, loosen adjusting screw at tighter brake.
2. If equalization requires more than a few notches movement, retighten adjusting screw to a point for proper adjustment of that brake and equalize rear cable by loosening cable clamp screws at equalizer clevis and pulling downward on tight side of cable. It may be necessary to open clamp with a screwdriver to allow cable to equalize.
3. Tighten clamp screws on equalizer while parking brake lever is still in applied position. When parking brake lever is released, it should be possible to turn each rear wheel by hand without feeling drag when rear cable is pulled downward by hand, gripping cable midway between conduit and guide on frame.
4. Close adjustment for tension may be secured by adjusting the clevis at the rear end of the front cable. In adjusting here, be certain to turn clevis without twisting cable.

1963 Tempest

The parking brake cable is properly adjusted when a 30-lb downward pull (using spring scale) on cable 49" from front of torque tube places cable 2¼" below bottom of torque tube with parking brake cable fully released.

1. Adjust parking brake cable at equalizer as required to obtain proper tension.
2. Tighten lock nut to 5-10 ft-lbs. torque.
3. Be sure cable slides freely in equalizer.
4. Check to make sure wheels turn freely without brake drag.

POWER BRAKE UNIT, REPLACE

1963 Pontiac

1. If master cylinder is to be removed from power cylinder, be sure to retain the selective shims located between the two units. If shims are damaged during removal they must be replaced.
2. To remove the power cylinder, disconnect vacuum hoses from reservoir and vacuum pipe at intake manifold.
3. Disconnect pipe from master cylinder hydraulic port.
4. From inside car, remove clevis pin from brake pedal. Then remove four attaching nuts and remove power cylinder.
5. Reverse removal procedure to install the unit and torque attaching nuts to 20-35 ft. lbs. Adjust pedal clevis to provide 3⅛ to 3⅜" from floor mat to bottom of pedal pad. Adjust stop light switch as required to provide 3/16" of plunger extending from body. Bleed brakes as necessary and fill fluid reservoir to 1" from top of filler hole.

1964-69 All Models

1. Disconnect vacuum hose at vacuum check valve. Plug hose and cover valve opening to exclude dust.
2. Disconnect pipe(s) from master cylinder hydraulic port and cover opening and pipe end to exclude dirt.
3. Remove clevis pin from brake pedal inside car.
4. Remove nuts from rear half housing and remove power cylinder assembly.
5. Reverse removal procedure to install.

BRAKE MASTER CYLINDER, REPLACE

1966-69

1. Disconnect brake lines from two outlets on master cylinder and tape end of lines to prevent entrance of dirt.
2. Disconnect master cylinder push rod from brake pedal.
3. Remove master cylinder from dash.

1963-65

To remove the master cylinder, disconnect the wires from the stop light switch and the brake tubes at the master cylinder connector. Remove the brake pedal-to-push rod clevis pin and disconnect the brake pedal retracting spring. Unfasten the master cylinder from its mounting and lift it off the car. Install in the reverse order.

Front Suspension & Steering Section

FRONT SUSPENSION

1963 Pontiac & All 1964-69

The front suspension is of the conventional "A" frame design with coil springs and ball joints. The ball joints have a "fixed boot" grease seal for protection against the entry of dirt and water. The steering knuckles and spindles are of integral design and brake cylinders are rigidly attached to the knuckles with the backing plates serving principally as a support for brake shoes and as a protective cover.

Rubber bushings at the inner ends of the upper control arms pivot on shafts attached to the car frame. Caster and camber adjustments are made with shims at this point, Fig. 1. Direct acting shock absorbers operate within the coil springs.

1963 Tempest

As shown in Fig. 2, stamped steel suspension control arms are used with rubber bushed mounting shafts. A strut bolted to the lower control arm is mounted at the rear with rubber bushings while the inner end is threaded so that the front suspension caster angle may be readily adjusted by varying the effective length of the strut. The coil springs are seated on the lower control arm and the shock absorbers operate within the coils. To completely isolate the body from road noise, the tops of the springs are seated against rubber insulators. Half ball joints with phenolic seats and anti-dive suspension geometry are also features of this system.

Fig. 1 Disassembled view of front suspension. 1963 Pontiac & all 1964-69 (typical)

LUBRICATION

These cars are completely lubricated at the factory with a special long-lasting chassis grease and under normal conditions chassis lubrication will not be required for 12,000 miles or one year whichever comes first. For subsequent lubrications, the specially formulated grease is recommended and is available at Pontiac dealers.

NOTE: If conventional chassis lubrication is used, relubrication at six months or 6000 miles, whichever occurs first, is necessary.

WHEEL ALIGNMENT

1963-69 All Models

Caster and camber adjustments are made by placing shims between the upper pivot shafts and frame, Fig. 3. Both adjustments can be made at the same time. In order to remove or install shims, raise car to remove weight from front wheel, then loosen control arm shaft-to-frame bolts.

1. To decrease positive caster add shims to front bolt.
2. To increase positive caster remove shims from front bolt.
3. To increase camber remove shims from both front and rear bolts.
4. To decrease camber add shims to both front and rear bolts.
5. Compensate for drift to right due to road camber by setting left angle ¼° greater than right.

NOTE: By adding or subtracting an

Fig. 2 Front suspension components. 1963 Tempest

Fig. 3 Caster and camber shim location

equal amount of shims from front and rear bolts, camber will be changed without affecting caster.

6. After the correct number of shims have been installed, torque pivot shaft mounting bolts to 55-75 ft-lbs.

TOE-IN, ADJUST

1. With wheels in straight ahead position, loosen tie rod clamp bolts and turn tubes an equal amount until toe-in is according to specifications. Turn right tie rod in direction of forward rotation of wheels to increase toe-in. Turn left tie rod in opposite direction to increase toe-in.
2. Tighten tie rod adjuster sleeve bolts to 14-20 ft-lbs, making sure bolts are to lower rear side of tie rod.

WHEEL BEARINGS, ADJUST

Hand Feel Method

1. Tighten spindle nut with an 8″ or 10″ wrench, using enough arm length leverage to be sure parts are properly seated while rotating wheel.
2. Back off nut finger loose, then tighten finger tight.
3. If hole in spindle lines up with slot in nut, install cotter pin. If not, back off to next slot and install cotter pin.

Torque Wrench Method

1. While rotating wheel (tighten nut with a torque wrench to 10-16 ft-lbs to be sure all parts are properly seated.
2. Back off adjusting nut finger free.
3. Tighten adjusting nut to 20-25 *inch-pounds.*
4. Loosen adjusting nut until nearest cotter pin hole lines up with a slot in nut and insert cotter pin.

WHEEL BEARINGS, REPLACE

(Disc Brakes)

1. Raise car and remove front wheels.
2. Remove brake hose support to caliper mounting bracket screw.
3. Remove caliper to mounting bracket bolts.

NOTE: Do not place strain on brake hose.

4. Remove spindle nut, and disc and hub assembly. Grease retainer and inner bearing can now be removed.

CHECKING BALL JOINTS FOR WEAR

Before checking ball joints for wear, make sure the front wheel bearings are properly adjusted and that the control arms are tight.

Fig. 4 Checking ball joints for wear

Referring to Fig. 4, raise wheel with a jack placed under the lower control at the point shown. Then test by moving the wheel up and down to check axial play, and rocking it at the top and bottom to measure radial play.

1. Upper ball joint should be replaced if there is any noticeable looseness at this joint.
2. Lower ball joint should be replaced if radial play exceeds .250″.

Fig. 5 Hydraulic control valve components. 1963 Tempest

3. Lower ball joint should be replaced if axial play between lower control arm and spindle exceeds the following:
   1963 Tempest ..... .093″
   1963 Pontiac, All 1964-69 ... .050″

BALL JOINTS, REPLACE

On all models the upper ball joint is riveted to the control arm. All service ball joints, however, are provided with bolt, nut and washer assemblies for replacement purposes.

The lower ball joint is pressed into the control arm. They may be pressed out and new joints pressed in.

NOTE: On 1965 full size Pontiacs a late type lower control arm is being used for increased durability. It incorporates a ball joint plate welded into the arm. Use of the plate makes it impossible to remove and replace the ball joint. Therefore, anytime it is necessary to replace a ball joint, the complete lower control arm assembly which includes the ball joint, must be replaced.

SHOCK ABSORBER, REPLACE

Hold the shock absorber upper stem from turning with a suitable wrench and remove the nut and grommet. Unfasten the lower shock absorber pivot from the lower control arm and pull the shock absorber and mounting out at the bottom of the spring housing.

To install, reverse the removal procedure. Tighten the upper retaining nut until it bottoms on the shoulder of the stem. Torque the nut to 4-6 lb. ft. and stake in place.

COIL SPRING, REPLACE

1. Remove shock absorber.
2. Jack up car and place stand jacks under frame side rails.
3. Remove wheel assembly to avoid damage to ball joints during spring operations.
4. Loosen 4 lower control arm cross shaft bushing bolts.
5. Install Special Spring Compressor or its equivalent through shock absorber mounting hole in front cross member and through spring. Install plate, thrust washer and nut and tighten so the spring is compressed slightly.
6. Remove nut from lower ball joint. Loosen the stud by hammering on the side of the steering knuckle joint boss, backing up the knuckle with a heavy hammer.
7. Remove upper ball joint stud in similar manner, and hang drum and knuckle assembly so as not to place a strain on brake hose.
8. Unfasten lower control arm inner shaft from frame cross member.
9. Unscrew spring compressor nut and remove spring from vehicle.
10. Installation is made in the reverse order of removal with the aid of the spring compressor. Rotate spring to be certain it fits the helical seats in both the cross member and lower control arm.

STEERING GEAR, REPLACE

1963 Tempest

1. Remove steering wheel.
2. Unfasten gear from frame and remove gear and shaft from car.
3. Remove plastic collar and felt seal from column.
4. Reverse removal procedure to install gear and tighten attaching bolts to 70-90 ft. lbs.

1963 Pontiac & All 1964-69

1. Use puller to remove pitman arm from steering gear shaft.
2. Scribe a mark on worm shaft flange and steering shaft and disconnect lower flange from steering shaft.
3. Unfasten gear housing from frame (3 bolts) and remove from car.

POWER STEERING UNIT, REPLACE

1963 Pontiac & 1964-69 All

1. Disconnect pressure and return hoses from gear housing.
2. Raise vehicle and disconnect pitman arm from shaft.
3. Scribe a mark on steering shaft worm shaft flange and disconnect flexible coupling from steering shaft.
4. Remove gear housing-to-frame bolts, noting number and location of gear-to-frame shims (if any). On 1969 Pontiac models a brake hose bracket must be removed prior to removing frame bolts.

NOTE: Metal-to-metal contact between flanges of stub shaft and steering shaft will transmit and amplify gear noise to driver. Therefore, when installing the gear, align steering column jacket, shaft and steering gear so head of lower coupling bolt has ¼″ clearance from flange on steering shaft. Adjust mast jacket up or down to avoid metal-to-metal contact.

Fig. 6 Booster cylinder components. 1963 Tempest

Fig. 7 Power steering pump components

LINKAGE TYPE POWER STEERING

1963 Tempest

The power steering system consists of a pulley driven vane type pump, an oil reservoir which is part of the pump assembly, a double-acting power booster cylinder, and a hydraulic control valve.

With a pressure gauge in the pressure line between the pump and control valve, turn the steering wheel from one extreme to the other and note the pressure on the gauge while holding the wheel momentarily against each stop. Pressure should not be less than 775 psi.

Pump, Replace

1. Drain system by removing inlet hose. Disconnect outlet hose and connector.
2. Loosen pump bracket bolt, remove drive belt and pump assembly from car.
3. Install in reverse order of removal. Fill reservoir with Hydra-Matic fluid and run engine at a fast idle speed for 30 seconds. Refill pump and bleed system by running engine and turning steering wheel through entire range of travel to expel air. Check oil level and for leaks throughout system. Fig. 7 illustrates pump components.

Control Valve

Fig. 5 illustrates the components of the hydraulic control valve assembly. Because this valve is adjustable, it must be adjusted after being assembled. *The following steps should be followed in balancing a control valve. The same procedure may be followed to correct a complaint of harder steering effort required in one direction than the other.*

1. Install valve in vehicle. Connect all hoses and fill pump reservoir with oil. Do not connect the cylinder rod to the frame bracket. If the vehicle is already in operation, it will be necessary to detach the cylinder rod from the frame bracket.
2. With all hoses attached and proper amount of oil added to the system, the engine should be started with the car on a hoist. One of the two following conditions will exist.
3. If the piston rod remains retracted, the adjusting nut should be advanced until the rod starts to move out. The nut should then be backed off until the rod starts to move in. Reposition the nut to exactly ½ the rotation required to change direction of shaft movement.
4. If the piston rod extends upon starting the pump, the adjusting nut should be retarded until the rod starts to move in. The nut should then be advanced until the rod starts to move out. Reposition the nut to exactly ½ the rotation required to change the direction of shaft movement. *Do not turn the nut back and forth more than is necessary to balance the valve.*
5. When valve is balanced, piston rod should be able to be moved in and out manually.
6. The engine should then be turned off and the cylinder rod connected to the frame bracket.
7. Check by starting the engine with car on a hoist. If front wheels do not turn in either direction from center, valve action is correct. Install dust cap on end of valve.

Booster Cylinder

If repairs are to be made to the booster cylinder, refer to Fig. 6 for proper location of components.

SERIAL NUMBER LOCATION: 1963-68 Stamped on plate attached to top of right front wheelhouse panel under hood.

1969: Plate is attached to top of instrument panel, on driver's side.

ENGINE IDENTIFICATION

6-196: The engine code number is located on a machined surface on the upper left front corner of the engine block. The letter "A" included as part of the number identifies the engine as the side-valve type; the letter "C" the overhead valve type.

6-199 & 6-232: The engine code number is located on a machined pad adjacent to the distributor. The letter contained in the code number identifies the cubic inch displacement of the engine. The letter "J" denotes the 199 engine with 8.5 compression ratio. The letter "L" denotes the 232 engine with 8.5 compression ratio.

V8-287 & 327: The engine code number is located on a tag attached to the alternator mounting bracket. The letter contained in the code denotes the size of the cylinder bore and compression ratio. The letter "E" denotes the 4" bore with 8.7 compression ratio (327 engine). The letter "F" denotes the 4" bore with 9.7 compression ratio (327 engine). The letter "G" denotes the 3¾" bore with 8.7 compression ratio (287 engine).

V8-290, 343 & 390: The engine code is located on a plate attached to the front of the right-hand rocker arm cover. The letter "H" four-barrel carburetor. The letter "Z" is for the 343 engine with four-barrel carburetor; "S" for two-barrel carburetor. The letter "W" is for the 390 engine with two-barrel carburetor in 1968 and four-barrel in 1969; "X" with four-barrel carburetor in 1968.

GENERATOR AND REGULATOR SPECIFICATIONS

★To Polarize Generator: For internally grounded systems, disconnect field lead from regulator and momentarily flash this lead to the regulator battery terminal. For externally grounded systems, reconnect the leads to the regulator; then momentarily connect a jumper wire from the "Gen" (Delco-Remy) or "Arm" (Auto-Lite) to the "Bat" terminals of the regulator.

COOLING SYSTEM & CAPACITY DATA

★NOTE: Alcohol should not be used in Rambler engines having aluminum components in contact with the coolant. When only water is used a good corrosion inhibitor must be added to the system. Failure to use an inhibited coolant may result in severe corrosion damage to the cooling system components.

①—With alcohol-type anti-freeze use a 170° unit.
②—Add one quart with filter change.
③—Cast iron block engine.
④—Aluminum block engine.
⑤—With L-head 6 engine.
⑥—With OHV-6 engine.
⑦—17 gals. for 3-seat wagon.
⑧—19 gals. for 3-seat wagon.
⑨—American 16.
AMX and Javelin 19.
Rebel & Ambassador 21½.
3-Seat Wagon 19.
⑩—Approximate. Make final check with dipstick.
⑪—Rambler Rogue with 6-232 uses 205°.
⑫—Rambler 16.
AMX and Javelin 19.
Rebel 3-seat wagon and Amb. wagon 19.
All Others 21½.
⑬—Fully synchronized 2½.
⑭—With 2 barrel carb. 9; with 4 barrel carb. 11.

②—3/32" on Rebel Six.
③—2/62" on V8-343, 390 wagons.
④—7/8" on Rambler, Javelin and AMX.

Electrical Section

IGNITION TIMING

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder is at the ignition timing point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

DISTRIBUTOR, REPLACE

1. Disconnect distributor primary wire from coil terminal.
2. Remove distributor cap and rotor. *Mark position of rotor arm on distributor housing so distributor can be installed in same position.*
3. Remove vacuum line from distributor.
4. Remove distributor hold-down clamp.
5. Note relative position of distributor in block, then work it out of the engine.

Installation

1. Turn rotor about 1/8 of a turn coun-

terclockwise past the mark previously placed on the distributor housing.
2. Push the distributor down into the block with the housing in the normal "installed" position. *On gear-driven distributors, it may be necessary to move the rotor slightly to start gear into mesh with camshaft gear, but rotor should line up with mark when distributor is down in place.*
3. Tighten distributor clamp screw snugly and connect vacuum line, primary wire to coil, and install cap.

V8 Note

If the engine was disturbed while the distributor was removed from the engine, first crank the engine to bring No. 1 piston up on its compression stroke and continue cranking until the timing mark is adjacent to the timing indicator. Then rotate the distributor cam until the rotor is in position to fire No. 1 cylinder. Install the distributor as outlined above and set the ignition timing as directed below.

STARTER, REPLACE

To remove starter, disconnect cable from battery. Disconnect cable and solenoid lead wire from solenoid switch. Remove starter attaching bolts and take off starter.

IGNITION SWITCH, REPLACE

NOTE: After the switch is removed the lock cylinder can be removed from the switch by inserting a paper clip through the small hole in the face or side of the switch. Then depress the lock pin and remove the lock.

1969 Rebel & Ambassador

1. Remove escutcheon nut from switch.
2. Disconnect wires and remove switch.

1967-68 All; 1969 AMX, Javelin & Rambler

Remove ignition switch from rear of instrument panel by holding switch escutcheon while pressing switch assembly toward instrument panel and turning counterclockwise.

The multi-wire connector on the switch should be removed after the switch is removed from the instrument panel. The multi-wire connector is locked to the switch by plastic fingers which are part of the connector and must be released before removing the connector.

NOTE: The AMX and Javelin have a separate ground wire added to the ignition switch plate.

1963 American

1. Disconnect a battery cable.
2. Disconnect ignition switch wires and remove switch retainer nut.
3. Withdraw switch from panel.

All 1966; 1963-65 Classic, Marlin & Ambassador

1. Disconnect a battery cable.
2. Disconnect switch wires.
3. Compress switch from rear, turn clockwise and remove switch from rear. Switch bezel is removed from front.

1964-65 American

1. Disconnect a battery cable.
2. Compress switch and turn it counterclockwise. Switch will then come out through rear.
3. Remove wires from switch.

LIGHT SWITCH, REPLACE

1963-64 Classic & Ambassador

1. Disconnect a battery cable.
2. With switch in full "Off" position, press button provided on side or top of switch to release shaft and knob assembly.
3. Remove two screws holding switch and bracket to panel.
4. Reverse above procedure to install. Position switch so that shaft is lined up properly before tightening bracket.

1964 American & All 1965-68

1. Disconnect a battery cable.
2. With switch in full "Off" position ("On" position for 1969 models) press button on side or top of switch to release shaft and knob assembly.
3. Remove switch mounting sleeve nut.
4. Disconnect wire harness connector.
5. Reverse procedure to install. Position switch so that shaft is lined up properly before tightening.

STOP LIGHT SWITCH, REPLACE

When replacing the switch, have the new switch ready for installation as soon as the old switch is removed from the master cylinder to avoid undue loss of brake fluid.

NEUTRAL SAFETY SWITCH

1964-69 Console Type

The switch is located on the right side of the selector shaft under the console. It also functions as a back-up light switch, therefore, the following adjustments will automatically adjust the back-up light switch for proper contact when the shift lever is in the "R" position.

1. Remove selector knob from shaft.
2. Unfasten and lift console up and over selector shaft.
3. Place selector lever in neutral.
4. Use a $\frac{3}{32}$" drill as an aligning pin. Insert the pin in the hole on the face of the switch. If necessary, move switch until pin enters freely into hole in switch toggle. *Switch toggle must enter into slot of actuating tab.*
5. Secure two screws that fasten switch to pivot bracket and remove aligning pin.
6. When switch is adjusted properly, engine will start only in Park or Neutral.

1963-69 Steering Column Type

The neutral safety switch also functions as a back-up light switch (when the car is so equipped). Therefore, the following adjustments will automatically adjust the back-up light switch for proper contact when the gear selector lever is in the "R" position.

1. Loosen two screws that secure switch to steering jacket tube.
2. Place selector lever in "N".
3. Using a $\frac{3}{32}$" drill as an aligning pin, insert the pin in the hole on the face of the switch. If necessary, rotate the switch until the pin enters freely in the hole in the switch toggle.
4. Tighten the switch screws and remove aligning pin.

TURN SIGNAL SWITCH, REPLACE

1967-68 Non-Tilt Column

1. Disconnect a battery cable.
2. Remove cover and pull off steering wheel.
3. Remove cancelling cam, turn signal switch lever, hazard warning knob and light shield (if equipped).
4. Remove plastic trim that covers column support plate. Remove signal switch wiring harness protector from lower side of column. *Do not remove column support plate.*
5. Disconnect signal switch connector from main harness. Remove terminals from switch harness. *Do not cut switch harness wires.*
6. Remove upper bearing snap ring and flat and wave washers.
7. Remove turn signal cover by loosening switch screws until cover can be rotated counterclockwise and remove cover from column.
8. Remove switch from turn signal cover, noting position of shift gate, springs and upper bearing retainer.
9. Reverse procedure to install.

1967-68 Tilt Column; 1969 All

1. Perform steps 1 to 5 as outlined for non-tilt columns.
2. Remove turn signal cover, switch retaining screws and switch.
3. Reverse procedure to install.

1963-66

The turn signal switch is mounted to

a bracket at the upper end of the jacket tube just below the steering wheel, which must be removed to get at the switch.

The signal switch cam is installed with an interference fit on the lower section of the steering wheel.

In diagnosing turn signal problems, the fuse, bulbs, wiring a good ground should be checked. A known good signal switch can be connected to the signal switch wire harness connector to determine whether the switch is defective.

On models having a wire harness attach a piece of string or fine wire to the signal switch harness. Leaving the string or wire in the steering column serves as an aid in replacement of the switch.

HORN SOUNDER & STEERING WHEEL

Disconnect battery. Remove horn button or ring. This is retained by screws from under the steering wheel on some models and is rubber mounted and can be pulled up on others. Remove steering wheel with a puller. Note line up of dash marks on steering shaft and wheel and align these marks when wheel is installed.

INSTRUMENT CLUSTER

1967-68 American; 1969 Rambler

1. Disconnect battery.
2. Remove cigar lighter and ignition switch.
3. Remove W/S wiper switch knob.
4. Remove light switch knob and shaft.
5. Remove flasher unit.
6. Disconnect speedometer cable housing at rear of cluster.
7. Remove two Phillips head screws at top of cluster overlay.
8. Partially remove cluster from instrument panel to gain access for removal of cluster pin plug.
9. Remove cluster assembly.
10. Reverse procedure to install.

1967-68 Except American; 1969 Except Rambler

1. Disconnect battery.
2. Remove screws from cluster overlay.
3. Remove overlay.
4. Remove screws securing cluster to instrument panel.
5. Remove pin plug and cluster.
6. Disconnect speedometer cable and parking brake light.

IMPORTANT: Spring metal grounding clip is required between cluster and Weather-eye controls. Also between clock or tachometer on AMX, Javelin. Be sure to install clip upon assembly of cluster if it was removed.

1966 American

1. Disconnect battery.
2. Remove ash tray and bracket, radio and instrument cluster overlay panel.
3. Remove Weather Eye console, bulb and socket.
4. On A/C cars, the air discharge outlet assembly and glove box must be removed. For access to the center attaching screw of the air discharge outlet, remove center discharge outlet bezel and vent assembly.
5. Disconnect speedometer cable and printed circuit plug. Remove wire harness clips attached to cluster.
6. The light switch, ignition switch and windshield wiper control need only be removed from the mounting on the panel and placed aside to provide clearance for removal of cluster.
7. Mask or tape cluster lens to prevent scratches.
8. Pull down on cluster to remove two upper tabs from slotted rubber mounting brackets.
9. Route cluster through rear of instrument panel and remove at bottom center. On A/C cars the cluster must be routed over the A/C evaporator and removed through glove box opening.

1965-66 Classic

1. Disconnect battery.
2. Remove flasher harness and printed circuit connectors and speedometer cable.
3. Remove two $\frac{5}{16}$" hex screws holding wire harness to rear of cluster.
4. Remove instrument cluster opening moulding with a fiber stick.
5. Remove four screws holding instrument panel bezel overlay to panel.
6. Mask panel lens to prevent scratches.
7. Remove four screws that hold cluster to panel.
8. On air conditioned cars remove discharge grille assembly.
9. Cluster and bezel assembly is then removed from front of panel.

1965-66 Ambassador & Marlin

1. Disconnect battery.
2. Remove flasher harness and printed circuit connectors and speedometer cable.
3. Remove two $\frac{5}{16}$" hex screws holding wire harness to rear of cluster.
4. Remove windshield wiper control.
5. Remove cluster opening inner and outer mouldings with a fiber stick.
6. Remove two cluster bezel screws.
7. Remove screws holding cluster bezel to panel.
8. If equipped with air conditioning, remove discharge grille or cover used in its place when not so equipped.
9. On cars with automatic transmission column shift and adjustable tilt wheel, steering column mounting bracket bolts should be loosened to allow clearance for cluster and bezel to be removed.
10. Remove cluster from bezel.

1963 American

To remove the cluster, disconnect battery and remove wires and speedometer cable from instrument cluster. Unfasten instrument cluster (2 screws) and slide cluster downward out of two upper tab retainers and grommets.

1963-64 Rambler

1. Disconnect battery.
2. Remove disconnect plug from rear of cluster. Disconnect speedometer cable.
3. Disconnect two panel light wires.
4. Remove three screws holding cluster hood top to panel. Lift hood up to disengage flange from groove.
5. Remove two screws holding cluster in place. Then lift cluster to disengage tabs, tilting unit to the right and out through face of panel.

1965 American

1. Disconnect battery and remove ignition switch and headlamp switch.
2. Remove fan temperature knob air and defroster control knob.
3. Disconnect speedometer cable, instrument cluster harness plug and flasher harness plug.
4. Remove air and defroster control assemblies and blower switch.
5. Remove two screws (top front side) holding cluster in place.
6. Mask cluster and bezel opening to prevent scratches. Cluster is then removed through front bezel opening.
7. Service instruments as required and install cluster in reverse order of removal.

W/S WIPER MOTOR, REPLACE

1963 American

The windshield wiper motor is mounted to the motor access hole cover plate with two machine screws. The plate is fastened to the dash panel under the instrument panel.

1. Remove the radio and/or bezel.
2. On models with air conditioning, the whole air conditioning unit must be lowered from the dash to expose the wiper motor mounting plate lower screws.
3. Disconnect the pivot shaft links from the motor arm studs by removing the spring clips.
4. Remove the cover plate to motor and cover plate to dash mounting screws.

5. Open the wiper control and turn the motor arm to the vertical position. The cover plate then can be raised high enough that the upper end of the motor arm will pass through the cover plate hole. Then lower the plate to remove it from the wiper motor.
6. Feed additional wiper hose and control cable into the air intake chamber to allow the wiper motor to be lowered to facilitate removing the wiper hose and control cable from the motor. The plastic cover must be removed before the control can be disconnected.

When installing the wiper motor, reverse the removal procedure. However, the wiper control cable must be installed with the washer at the end of the control wire inserted in the slot in the slide valve. The conduit must butt against the shoulders of the anchoring slot and be fastened securely to assure positive opening and closing of the valve for efficient operation.

1963-68 Rambler; 1969 Rebel & Ambassador

1. Remove wiper arms and blades and cowl air intake cover.
2. Slide link to motor retainer clip off motor arm stud which is accessible through cowl top opening. Remove link from motor.
3. On vacuum type motor, disconnect control cable and hose from motor, then remove motor and mounting plate from dash panel.
4. On 1965-69 models with electric wiper, disconnect switch-to-motor female connectors at switch and remove through main wire harness grommet. Remove wiper motor and mounting plate.
5. On 1963-64 models with electric wiper, separate wiper harness plug under instrument panel and pull harness and plug out of harness grommet. Remove wiper motor and mounting plate.

1964-68 American, AMX & Javelin; 1969 Rambler, AMX & Javelin

1. To remove wiper motor, remove four screws holding motor to dash panel.
2. Remove hose and control cable from vacuum type motor. On electric motors, separate wiper harness plug under instrument panel.
3. Tilt motor and slide link-to-motor retaining clip off of stud and remove motor.

W/S WIPER TRANSMISSION, REPLACE

1963-68 Rambler; 1969 Rebel & Ambassador

1. Remove wiper arms and blades.
2. Remove cowl air intake cover.
3. Disconnect link-to-motor retainer and link from wiper arm through cowl top opening.
4. Close hood and remove two capscrews holding each pivot shaft body to cowl top.
5. Remove both pivot body and link assemblies as a unit through cowl top opening.
6. Pivot shaft bodies may then be removed by sliding retainer off stud.

NOTE

When installing pivot shaft bodies to cowl top, the assist spring must be in a position to engage rubber sleeved stud on vacuum wiper. There are no assist springs on electric wipers.

1964-68 American, AMX & Javelin; 1969 Rambler, AMX & Javelin

1. Remove wiper arms and blades.
2. Remove pivot shaft-to-cowl top nuts.
3. Remove wiper motor.
4. Slide pivot shaft body and link assembly to the left to clear right pivot shaft opening and move assembly to the right side of car to remove as a unit.

NOTE

When installing pivot shafts to cowl top, flat side of pivot shaft indexes flat side of hole in cowl top when pivot shaft is in up position.

1963 American

1. Remove glove box and defroster hose.
2. Take off wiper arm and blade.
3. Remove pivot shaft-to-cowl top nut and spacer.
4. Disconnect link end from motor arm and remove pivot shaft and link assembly.
5. Reverse above procedure to install.

W/S WIPER CONTROL, REPLACE

1966-69 All Models

1. Remove control knob. The knob is retained either by a set screw or by a spring retainer. The spring retainer is released as follows: turn knob fully to right and insert Allen wrench in notch at small end of knob. Push toward shaft to raise spring out of groove and at same time pull knob off shaft.
2. On all models, after the knob has been removed, disconnect control cable from motor on vacuum wipers. On electric wipers, disconnect three female connectors from switch. Remove French nut to disengage switch from instrument panel.

NOTE: On vacuum wipers the control cable must be installed with the washer at the end of the control wire inserted in slot in slide valve. The conduit must butt against the shoulders of the anchoring slot and be fastened securely to assure positive opening and closing of the valve for efficient operation.

1964-65 Rambler

1. To remove control knob, loosen set screw and pull knob from shaft. The electric wiper knob has a finger tab to assist in turning control on whereas the vacuum unit does not.
2. After removing knob, disconnect control cable on vacuum wiper. On electric wiper disconnect wire harness plug and remove circuit breaker wire.
3. Remove instrument cluster hood.
4. Loosen instrument cluster and sealing tape and speedometer cable.
5. Move instrument cluster to one side. Control mounting screws then become accessible through instrument cluster opening.

NOTE

On vacuum wipers, control cable must be installed with washer at end of control wire inserted in slot in slide valve. The conduit must butt against shoulders of anchoring slot and be fastened securely to assure positive opening and closing of valve for efficient operation.

1964-65 American

1. To remove control knob, loosen set screw, insert an offset screwdriver or an Allen wrench into notch provided in small end of knob. Push down on spring retainer to release it from groove in shaft and pull off knob.
2. After removing knob, disconnect control cable from vacuum wiper. On electric wiper, disconnect wire harness plug and remove circuit breaker wire.
3. Remove slotted trim nut and remove control.

NOTE

On vacuum wipers the control cable must be installed with the washer inserted in slot in slide valve. The conduit must butt against shoulders of anchoring slot and fastened securely to assure positive opening and closing of valve for efficient operation.

1963 American

1. To remove control knob, insert a small drift into notch provided in small end of knob and push in on spring to release it from groove in shaft and pull off knob.
2. Remove wiper motor and disconnect control cable from motor.
3. Remove control-to-instrument panel nut.

NOTE

The plastic tube covering the cable must be anchored with the cable conduit to prevent moisture entering conduit at motor end. Control cable must be installed with washer at end of control wire inserted in slot in slide valve. Conduit must butt against shoulders of anchoring slot and be fastened securely to assure positive opening and closing of valve.

RADIO

NOTE: When installing radio, be sure to adjust antenna trimmer for peak performance.

1963 Rambler

1. Disconnect battery and remove antenna lead from radio.
2. Disconnect power lead from radio and unplug radio-to-speaker cable.
3. Pull off control knobs and control shaft bushing nuts.
4. Remove screw from rear radio brace.
5. Remove radio toward back and down from instrument panel.

1963 American

1. Remove radio control knobs.
2. Remove radio overlay (2 screws).
3. Remove two vertical screws holding radio to dash.
4. Unplug antenna, power and speaker leads and lower radio from dash.

1964-67

1. Radio is retained to instrument panel by the control shaft bushing nuts.
2. Disconnect battery and remove antenna lead from radio.
3. Disconnect power lead from radio and unplug radio-to-speaker cable.
4. Pull knobs from radio and remove control shaft bushing retainer nuts.
5. Radio can now be removed toward back and down from instrument panel.

NOTE: On Rambler models with A/C, it will be necessary to remove the A/C discharge outlet assembly and connecting duct. On American models with A/C it will be necessary to remove the glove box.

1968-69 Javelin & AMX

1. Remove the ash tray.
2. Remove the retaining bolt in the ash tray which is threaded into the radio. With AM-Tapeplayer combination this bolt is not used. A retaining nut is used on the rear of the radio and must be removed.
3. Remove the shaft retaining nuts.
4. Disconnect all leads from radio and tip the rear of the radio up and to the toe board and remove from the rear edge of the panel.

NOTE: If equipped with A/C the air discharge duct must be removed to gain clearance.

1968 American; 1969 Rambler

1. Disconnect battery and remove antenna lead from radio.
2. Disconnect power lead from radio and unplug radio-to-speaker cable.
3. Remove control knobs and control shaft bushing retainer nuts.
4. Remove ash tray.
5. Remove Phillips head screw which is threaded into cage nut on radio.
6. Radio can now be removed toward back and down from panel.

NOTE: If equipped with A/C it will be necessary to remove the glove box.

1968 Rambler
1969 Rebel & Ambassador

1. The radio is retained to the instrument cluster by four screws adjacent to the face of the radio and a brace rod from the rear of the radio down to the instrument panel flange.
2. Disconnect the battery.
3. Disconnect antenna, power, ground and speaker leads from radio.
4. On 1968, remove brace bracket rod from instrument panel flange.
5. Remove instrument panel overlay and on 1968 models, remove instrument cluster.
6. Remove radio mounting screws and remove radio.

NOTE: Leads attached to radio must be drawn carefully through the opening while removing the radio to prevent damage to the wiring.

HEATER CORE REMOVAL

1965-68 American, AMX & Javelin; 1969 Rambler, AMX & Javelin

1. Open heater water valve and drain about 2 qts from cooling system.
2. After disconnecting hoses from heater core, install cork plugs in hoses and core tubes.
3. Disconnect blower motor wires and ground wire to dash panel.
4. Remove glove box and its door. On AMX and Javelin, it is necessary to remove glove box hinge bracket.
5. Disconnect outside air control cable at damper lever.

Fig. 1 Centering spring adjustment. 1967-69

6. Remove three heater housing attaching screws in front compartment and lift out heater core and blower housing assembly.
7. Heater core is now accessible for removal.

1965-68 Except American; 1969 Rebel & Ambassador

1. Disconnect outside air damper cable at heater housing under dash.
2. Drain system and disconnect hoses.
3. Remove two lower attaching nuts for blower housing in engine compartment.
4. Remove glove box and door in order to remove remaining heater housing screws and lower heater and core housing as an assembly.
5. Slide heater core out of housing.

1963-64 Rambler

1. Drain system and disconnect water hoses, then remove two screws that attach blower motor to engine side of dash.
2. Inside car, remove heater housing and slide out core. On 1964 models, it is necessary to remove glove box.

1964 American

Remove glove box, drain system & unfasten hoses, then take out entire heater and defroster assembly to gain access to the heater core.

SPEED CONTROL

1967-69

Brake Release Switch, Adjust

1. Disconnect multiple connector at regulator.
2. Turn ignition switch to accessory position.
3. Using a test lamp, ground one test lamp lead and touch the other to terminal No. 2 in harness connector.
4. Adjust switch so that lamp will light when brake pedal is fully released and will go out when brake pedal is depressed about ¼ inch.
5. If switch cannot be adjusted, it is defective and should be replaced. Install new switch and repeat Step 4.
6. Remove test lamp, turn off ignition key and plug connector to regulator.

Chain Linkage, Adjust

Chain linkage should never be taut. To adjust, start engine, set carburetor at hot idle with anti-stall plunger backed off so as not to affect idle speed. Hook chain to accelerator linkage, pull taut, then loosen by length of one ball and install chain clip. *When pulling chain taut, do not pull so far as to cause throttle to open.*

Centering Spring, Adjust

If speed control system holds speed three or more mph higher than selected speed, turn centering spring adjusting screw (C) toward (S) $\frac{1}{32}$" or less, Fig. 1.
If speed control system holds speed three or more mph below selected speed, turn centering spring adjusting screw (C) toward (F) $\frac{1}{32}$" or less. *Do not move adjustment screw (R).*

Engine Section

ENGINE MARKINGS

Engines are stamped with a three-letter code which is stamped adjacent to the engine identification code number. The code is as follows:

First letter means size of bore.
Second letter means size of main bearings.
Third letter means size of rod bearings.
Letter "A" means standard size.
Letter "B" means .010" undersize.
Letter "C" means .010" oversize.
Engines not so marked are standard in all respects.

On six-cylinder engines a five digit engine code number is located on a machined surface on the upper left corner of the engine block. On V8 engines the engine code number is stamped on a tag attached to the generator mounting bracket.

ENGINE REPLACE

All Models

1. Mark hood hinge location on hood panel to aid in installation and remove hood.
2. Remove battery and drain cooling system and engine crankcase. On 1965-69 models also drain transmission.
3. Disconnect all wiring, tubing, hoses and linkage.
4. Disconnect exhaust pipe.
5. On 1963 American with L-head engine, the engine and transmission can be removed as a unit from below car as follows:
   a. Remove radiator and A/C compressor if so equipped.
   b. Attach lifting rig to cylinder head studs and raise car, preferably on a two post lift. Support front of car on high jacks located under body side sills just forward of front engine crossmember.
   c. Remove front suspension crossmember (K-brace) and disconnect steering linkage.
   d. Disconnect speedometer cable at transmission and remove parking cable linkage from rear crossmember.
   e. Attach block and tackle to lifting rig and adjust to support engine weight.
   f. Disconnect front and rear members from side sills and while lowering engine slightly to a forward position, the U-joint can be slipped from transmission mainshaft.
   g. Engine can then be lowered completely. **NOTE:** Upon installation, front suspension alignment must be checked.
6. On all other models, remove air cleaner and radiator.
7. If equipped, remove power steering pump and air conditioning compressor and condenser.
8. On 1963 Rambler and all 1964 models, remove flywheel underpan and starting motor. From this point flywheel housing must be supported at all times.
9. Attach lifting fixture to engine.
10. On 1963 Rambler and all 1964 models, remove flywheel housing to engine block screws and if equipped with automatic transmission remove screws from flywheel drive plate to converter.
11. On all other models, remove rear crossmember and disconnect torque tube, where used, from transmission extension.
12. On 1965-69 V8 models, disconnect brake tube bracket fastened to underside of body, disconnect shock absorbers at lower bracket, parking brake cable at equalizer and cable housing at torque tube bracket.
13. Also on 1965-69 V8 models, move rear axle rearward to remove front U-joint from transmission mainshaft. After disconnecting speedometer cable from transmission.
14. Disconnect front engine support cushions from engine and lift engine forward and upward through hood opening while supporting propeller shaft.

CYLINDER HEAD

Tighten cylinder head bolts a little at a time in three steps in the sequence shown in the illustrations. Final tightening should be to the torque specifications listed in the *Engine Tightening* table.

V8-290, 343, 390

The cylinder block has two locating dowels on each bank to assist in lining up and holding the cylinder head and gasket in position during installation.

IMPORTANT: The No. 7 bolt shown in Fig. 7, second from front on the left bank, must have the threads sealed to prevent coolant leakage. Permatex No. 2 or equivalent is recommended.

V8-287, 327

The cylinder head block surface has two locating dowels to assist in lining

Engine oiling system. OHV 6-196 with cast iron block

Aluminum block OHV 6-196 engine oiling system

up and holding the position of the head and gasket during installation and removal.

After installing push rods, rocker arms and cylinder head cap screws, tighten the cap screws in the sequence shown in Fig. 1, and to the torque values given in the *Engine Tightening Chart.*

The cylinder head and rocker arm cap screws are of various lengths and design, among which are two special tapped heads to accommodate the retaining screws that hold the rocker arm cover; three long plain cap screws to retain rocker arms and cylinder head, and one special bolt to index with oil holes for rocker arm lubrication. *This special 6⅜" long drilled bolt is part of the lubrication system and must be installed in the rear position to index with oil passages in the tappet area.*

6-196 Engines

Tighten cylinder heads in the order shown in Figs. 2, 3, 4 and to the torque given in the *Engine Tightening Chart.* On overhead valve engines be sure to adjust the valves after the tightening operation.

Fig. 1 Cylinder head tightening sequence and bolt length chart. 8-287, 327

Aluminum Block 6-196

On the aluminum block six-cylinder engine, hollow guide pins are located at the right front and right rear corner of the cylinder block to insure correct cylinder head location.

The guide pin located at the right front corner of the block is also the oil delivery tube to the rocker arm shaft assembly. Two neoprene oil rings form a seal between the guide pin, block and head. These O-ring seals must be replaced each time the cylinder head is removed. The correct procedure is as follows:

1. Remove the tube by grasping with a pair of pliers, being careful not to damage the tube. Gently turn the tube in each direction while pulling outward.
2. Install O-rings on tube and apply a generous amount of engine oil to the assembly.
3. Tap tube lightly into cylinder block bore one-half its length as shown in Fig. 5.

Fig. 2 Cylinder head tightening sequence. Flat head six

Fig. 3 Cylinder head tightening and bolt length chart. OHV 6-196 cast iron engine

4. After cleaning top surface of block and bottom surface of cylinder head, inspect both for smooth flat surfaces with a straight edge.
5. Apply sealing compound to both sides of head gasket. Place head on block, being careful not to damage upper O-ring.
6. Tighten capscrews in 20 pound increments until the recommended torque is reached in the sequence shown in Fig. 4. Recheck cylinder head torque when engine reaches normal operating temperature.

6-199, 6-232 Engines

IMPORTANT: The cylinder head bolt located at the left front corner of the head (No. 11, Fig. 6) must have the threads sealed to prevent coolant leakage. Permatex No. 2 or equivalent is recommended.

ROCKER ARMS

V8-290, 343, 390

These engines have individually mounted rocker arms consisting of a rocker arm retaining stud, rocker arm pivot ball, rocker arm and retaining nut to operate each valve, Fig. 8.

The rocker arm studs are threaded into the cylinder head. The threads are of such design to cause an interference fit; therefore, care must be taken that replacement studs be installed until the hexagon head is flush with the cylinder head and torqued to 65-70 ft-lbs.

The push rods are hollow, serving as oil galleries for lubricating each individual rocker arm assembly. Prior to installing, the push rods should be cleaned thoroughly, inspected for wear and deposits which may restrict the flow of oil to the rocker arm assembly.

The push rods also serve as guides to maintain correct rocker arm to valve stem relationship; therefore, a contact pattern on the push rods where they contact the cylinder head is normal.

When installing the rocker arm retaining nut, it is important that they be tightened until bottomed, using a torque of 20-25 ft-lbs.

Lubrication to each rocker arm is supplied by the corresponding hydraulic valve lifter. A metering system located in each valve lifter consists of a stepped lower surface on the push rod cap that contacts a flat plate, causing a restric-

Fig. 12 Rocker arm assembly. 6-199, 232 engines

Fig. 13 Rocker arm assembly. V8-287, 327 engines

tion, Fig. 9. The restriction meters the amount of oil flow through the push rod cap, hollow push rod, and upper valve train components. A loss of lubrication to the rocker arm could be caused by a restricted or plugged push rod or a defective hydraulic valve lifter.

CAUTION: Correct installation of push rods in these engines is critical and more than normal care must be taken upon installation. When placing the push rods through the guide hole in the cylinder head, it is important that the push rod end is inserted in the plunger cap socket. It is possible that the push rod may seat itself on the edge of the plunger cap which will restrict valve lifter rotation and lubrication to rocker arms.

It is recommended that, just prior to installation of the cylinder head covers, the engine be operated and the supply of lubrication to each rocker arm be visually inspected. If inspection reveals that an individual rocker arm is not being supplied with lubrication, the push rod and/or valve lifter must be inspected to determine the cause.

Fig. 9 Hydraulic lifter identification. V8-290, 343 engines

OHV 6-196 Engine

The entire rocker arm and valve assembly is lubricated by oil under pressure from the oil pressure gallery, directed through an opening provided in the cylinder head, then through the front rocker arm shaft support block.

The rocker arm shaft must be installed with the rocker arm lubricating oil holes located to the bottom of the shaft, Fig. 10.

6-199, 6-232 Engines

The pressure supply for each rocker arm is obtained from No. 5 camshaft bearing location where the camshaft meters the flow of oil from the main lubrication gallery through a groove in the camshaft bearing surface to a gallery extending upwards to the cylinder head gasket surface, Fig. 11. When installing the rocker arm shaft the oil holes must face down to the cylinder head, Fig. 12.

V8-287, 327 Engines

The rocker arm shaft assemblies are secured to the cylinder head with four long cylinder head and rocker arm shaft retaining screws, Fig. 13. The shafts are hollow and plugged at each end, serving as oil galleries for rocker arm, push rod end and valve stem lubrication.

Two different rocker arms are used to accommodate the angle from the shaft support to valve stems. However, the shaft assemblies are interchangeable from one cylinder bank to the other.

VALVE GUIDES

V8-290, 343, 390

6-196 With Aluminum Block, 6-199, 6-232 Engines

Excessive valve stem-to-guide clearance will cause lack of power, rough idling and noisy valves, and may cause valve breakage. Insufficient clearance will result in noisy and sticky functioning of valves and disturb engine smoothness of operation.

Valve stem-to-guide clearances are listed in the *Engine Valve Specifications* table. By using a micrometer and a suitable telescope hole gauge, check the diameter of the valve stem in three places (top, center and bottom). Insert telescope hole gauge in valve guide bore, measuring at the center. Subtract the highest reading of valve stem diameter from valve guide bore center diameter to obtain valve-to-guide clearance. If clearance is not within specified limits, use the next oversize valve and ream bore to fit. Valves with oversize stems are available in .003", .015" and .030".

6-196 OHV With Cast Iron Block & V8-287, 327

Valve guides are removed and replaced with special pullers and drivers made for the purpose. If this equipment is not available, carefully measure with a steel scale the amount each guide projects from the valve port before removing it so that the position of the new guide will be properly located when it is driven in. After the new guides are installed, they should be reamed to provide the clearance within the limits given in the *Valve Specifications* chart.

Fig. 10 Rocker arm shaft assembly sequence (one end shown). 6-196 engine

Fig. 11 Rocker arm lubrication gallery. 6-199, 232 engines

Fig. 14 Hydraulic valve lifter

VALVE LIFTERS

Mechanical Lifters

Since these lifters are of the mushroom type and the guides are cast integral with the cylinder block, it is necessary to remove the camshaft before the lifters can be taken out. Follow the instructions for removing the camshaft under that heading; then remove the oil pan and take the lifters out through the bottom.

To make removal of the camshaft easier, hold up the lifters with rubber bands on overhead valve engines.

Fig. 16 Valve timing. V8 engines

Fig. 15 Timing chain cover assembly. V8-290, 343, 390 engines

Hydraulic Lifters

Valve lifters may be removed from their bores after removing the rocker arms and push rods. Adjustable pliers with taped jaws may be used to remove lifters that are stuck due to varnish, carbon, etc. Fig. 14 illustrates the type of lifter used.

TIMING CHAIN COVER

V8-290, 343, 390 Engines

The timing chain cover is a die casting incorporating an oil seal at the vibration damper hub, Fig. 15. The crankshaft front seal is installed from the back side of the cover, therefore, it is necessary to remove the cover when replacement of the seal is required. To remove cover, proceed as follows:

1. Drain cooling system completely.
2. Remove lower radiator hose and bypass hose from cover.
3. Remove distributor, fuel pump, drive belts, fan and hub assembly and vibration damper, using a suitable puller.

NOTE: It is not necessary to disconnect power steering or discharge air conditioning system (if equipped). Remove units from their mounting brackets and place them aside.

4. Remove two front oil pan bolts and the eight hex head bolts retaining the cover to the cylinder block.
5. Pull cover forward until free from locating dowel pins.
6. Remove used seal and clean seal bore and gasket surface of cover.
7. Apply sealing compound to outer surface of seal and a film of Lubriplate or equivalent to seal lips. Drive seal into cover bore until seal contacts outer flange of cover.

Installation of Cover

1. Prior to installation of cover, remove lower dowel pin from cylinder block.
2. Using a sharp knife or razor blade, cut oil pan gasket flush with cylinder block on both sides of oil pan.
3. Cut corresponding pieces of gasket from the replacement oil pan gasket set. Cement gasket to cover. Install replacement Neoprene oil pan seal into cover and align cork gasket tabs to the pan seal.
4. Apply a strip of sealing compound to both the cut-off oil pan gaskets at the oil pan to cylinder block location.
5. Place cover in position, install oil pan bolts in cover, tighten evenly and slowly until cover aligns with upper dowel. Then install lower dowel through cover. Drive dowel in corresponding hole in cylinder block.
6. Install cover attaching bolts and torque to 20-30 ft-lbs.

Six Cylinder

NOTE: On 1963-66 models it is not necessary to remove the cover in order to replace the cover oil seal.

When installing the cover it is impor-

Fig. 17 Valve timing. 6-196, 199, 232 engines

Fig. 18 Piston and rod assembly. V8-290 with 2 barrel carburetor

Fig. 19 Piston and rod assembly. V8-290 with four barrel carburetor

Fig. 20 Piston and rod assembly. V8-343 engine

tant that the cover be properly aligned when installing the vibration damper to prevent damage to the oil seal. This is accomplished by leaving the cover-to-block cap screws loose until the vibration damper has been partially installed. Then tighten the cover screws.

SERVICE BULLETIN

New Gaskets. The design of the gasket between the timing case cover and the engine oil pan on the 199 and 232 cu. in. 1965 Rambler engines has been changed. For easier installation, two more retaining nibs have been added. This change also necessitated the addition of two more holes in the lower flange of the timing case cover. These increase the total to seven.

If a five-nibbed gasket is installed on a timing case cover with seven holes, it will be necessary to fill the two unused holes with a suitable sealant to eliminate any possibility of oil leakage.

Also, when a gasket with seven retaining nibs is being installed on an engine whose timing case cover has only five holes, the two unused nibs must be cut off flush with a sharp knife or razor.

TIMING CHAIN

When installing a timing chain, see that the timing marks on the sprockets are in line as shown in Figs. 16 and 17.

CAMSHAFT

To remove camshaft, remove all valve lifters. Take off timing chain and sprockets. Remove fuel pump, distributor and distributor-oil pump drive gear. When withdrawing camshaft from engine, use care to avoid damage to the camshaft bearings.

When installing the timing chain, be sure to align the timing marks as shown in Figs. 16 and 17.

Fig. 20A Piston and rod assembly. V8-390

Fig. 21 Piston and rod assembly. V8-287, 327 engines

PISTONS & RODS, ASSEMBLE

V8 Engines

Assemble piston to connecting rod as shown in Figs. 18 to 21.

Overhead Valve 6-Cyl.

Pistons are marked with a depression notch on the top perimeter, Fig. 22. When installed in the engine this notch must be toward the front of the engine. Always assemble rods and caps with the cylinder numbers facing the camshaft side of engine.

Side Valve 6

When installed, the identification knob on the connecting rod and the notch on the top of the piston must face front of the engine.

PISTONS, PINS & RINGS

Pistons are furnished in standard sizes and oversizes of .002, .005, .010 and .020″.

Piston pins are furnished in oversizes of .003 and .005″.

Piston rings are available in .020″ oversizes. On 1963-66 V8s a .030″ oversize is also available.

MAIN & ROD BEARINGS

Both main and rod bearings are supplied in undersizes of .001, .002, .010 and .012″.

CRANKSHAFT REAR OIL SEAL

199, 232, 290, 343, 390 Engines

1. To replace the seal, Fig. 23, remove

oil pan and scrape oil pan surfaces clean.
2. Remove rear main bearing cap.
3. Remove and discard old seals.
4. Clean cap thoroughly.
5. Loosen all remaining main bearing cap screws.
6. With a brass drift and hammer, tap upper seal until sufficient seal is protruding to permit pulling seal out completely with pliers.
7. Wipe seal surface of crankshaft clean, then oil lightly.
8. Coat back surface of upper seal with soap, and lip of seal with No. 40 engine oil.
9. Install upper seal into cylinder block. *Lip of seal must face to front of engine.*
10. Coat cap and cylinder block mating surface portion of seal with Permatex No. 2 or equivalent, being careful not to apply sealer on lip of seal.
11. Coat back surface of lower seal with soap, and lip of seal with No. 40 engine oil. Place into cap, seating seal firmly into seal recess in cap.
12. Place Permatex No. 2 or equivalent on both chamfered edges of rear main bearing cap.
13. Install main bearings and install cap. Tighten all caps to 75-85 ft-lbs.
14. Cement oil pan gasket to cylinder block with tongue of gasket at each end coated with Permatex or equivalent before installing into rear main bearing cap at joint of tongue and oil pan front neoprene seal.
15. Coat oil pan rear seal with soap. Place into recess of rear main bearing cap, making certain seal is firmly and evenly seated.
16. Install oil pan and tighten drain plug securely.

196, 287, 327 Engines

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing. Directly in front of this seal is an oil slinger which deflects the oil back into the oil pan. Should the braided seal require replacement, the installation of the lower half is accomplished as follows:

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position or roll it snugly in its groove with a smooth rounded tool. Then cut off the protruding ends of the seal with a sharp knife or razor blade.

OIL PAN

1968-69 Six

1. Disconnect front cushions from engine bracket.
2. Remove right bracket from engine.
3. Disconnect ground strap.
4. Remove cylinder head cover and air cleaner.
5. Disconnect fan shroud if so equipped.
6. Raise engine as far as possible.
7. Disconnect stabilizer bar from side sill if so equipped.
8. Loosen strut rod bolts at lower control arms.
9. Remove crossmember-to-side sill bolts.
10. With weight of car on wheels pry down crossmember, use wooden blocks to hold crossmember down.
11. Drain engine oil, remove oil pan.

Fig. 22 Piston and rod assembly. 6-196, 199, 232 engines

1968-69 V8

1. Turn crankshaft until mark on damper is 180° from timing marks on cover.
2. Disconnect cushions from crossmember.
3. Disconnect ground strap.
4. On American and 1969 Rambler, remove cushion brackets from cylinder block.
5. Remove starter motor.
6. Remove idler arm from side sill.
7. On Ambassador, disconnect stabilizer bar at side sills.

Fig. 23 Rear main bearing sealing. 199, 232, 290, 343, 390 engines

8. On 1968 models proceed as follows:
   a. On all except Ambassador, loosen stabilizer bar links to control arms as far as possible.
   b. Attach lifting fixture to engine and raise engine as far as possible.
   c. Loosen strut rod bolts at control arms.
   d. Remove crossmember side sill bolts and nuts.
9. On 1969 models proceed as follows:
   a. On all except Ambassador, disconnect sway bar brackets and shocks from lower control arms.
   b. Attach lifting fixture to engine and raise engine as far as possible.
10. On all models, remove crossmember to side sill bolts and pry crossmember down and insert wooden blocks to hold it down.
11. Drain oil and remove oil pan.

1967 Six and V8s

1. Remove front springs. Then support weight of car at front.
2. Support front of engine above engine compartment.
3. Remove front support cushions at engine.
4. Remove idler arm from bracket.
5. Remove front stabilizer bar (if equipped).
6. Unfasten front crossmember and pry it down to gain clearance for oil pan removal. Wooden spacer blocks installed between crossmember and body side sill will assist in holding crossmember down.
7. On six-cylinder models, remove flywheel dust cover.
8. Drain engine oil and remove pan.

6-196 C.I. Engine Note

Whenever the oil pan is removed it is important that the oil pan-to-rear bearing cap seal be replaced and a new seal be installed correctly.

The installation of the new seal is important as temperature and pressure from the oil pan cause the seal to retain a permanent shape which may not seal correctly upon the installation of the seal a second time.

It is advisable to apply a light film of Lubriplate on the two upper sections of the seal. This will allow the seal to be installed in position between the rear main bearing cap and cylinder block with ease and assist in forming a good sealed area.

1965-66 Ambassador V8

1. Drain engine oil and remove flywheel dust cover.
2. Disconnect front suspension stabilizer bar at rear mounting locations and allow bar to hang down.
3. Unfasten and remove oil pan.

1964-66 American, 1963-66 Classic & Marlin, 1963-64 Ambassador (All) & 1965-66 Ambassador 6 Cyl.

1. Remove front springs, then support weight of car at front.
2. Support front of engine from above engine compartment.
3. On 6-196 engines, remove engine support cushion nuts at engine mounting bracket. On other models, remove support cushion at engine.
4. Remove steering idler arm from bracket.
5. On Rambler models, remove sway stabilizer bar (if equipped).
6. Unfasten front suspension crossmember from body side sills.
7. Pry crossmember down to obtain clearance for oil pan removal.

NOTE: Wooden spacer blocks installed between crossmember and body side sill will assist in holding crossmember down.

8. Remove flywheel underpan.
9. Remove oil pan. On 6-196 engines, turn crankshaft so No. 1 piston is on upstroke, then remove oil pan.

1963 American

To remove the oil pan, it is necessary to remove the "K" frame member from the body side sills. Unfasten and lower the steering linkage. Then remove the oil pan.

OIL PUMP

6-199, 6-232 & V8s

Oil pump removal or replacement will not affect distributor timing as the distributor drive gear remains in mesh with the camshaft gear.

Upon disassembly of the oil pump, locate a straight edge across the pump body and gears in the body and check the gear-to-cover clearance, which should not exceed .004". A clearance of .008" maximum should exist between gears and walls of pump body.

The pump cover should be installed with the pump out of the engine and pump checked for freedom of operation before installation.

The oil pressure relief valve, which is built into the pump, is not adjustable, the correct pressure being built into the relief valve spring.

6-196 Engines

The oil pump on these models consist of a drive and driven gear. The drive shaft being keyed to the drive gear at the lower end, is driven by a gear at the upper end which engages with the camshaft gear. The distributor drive is taken from the top end of the oil pump drive shaft. A wire snap ring is used on the undercut on the lower end of the shaft to prevent the shaft from disengaging the lower gear when the oil pump is removed.

WATER PUMP

1. To remove the water pump, drain cooling system.
2. Remove fan belt, fan and pulley.
3. Unfasten and remove water pump from water manifold.

FUEL PUMP, REPLACE

1. Remove all gasket material from the pump and block gasket surfaces. Apply sealer to both sides of new gasket.
2. Position gasket on pump flange and hold pump in position against its mounting surface. Make sure rocker arm is riding on camshaft eccentric.
3. Press pump tight against its mounting. Install retaining screws and tighten them alternately.
4. Connect fuel lines. Then operate engine and check for leaks.

SERVICE NOTE: Before installing the pump, it is good practice to crank the engine so that the nose of the camshaft eccentric is out of the way of the fuel pump rocker arm when the pump is installed. In this way there will be the least amount of tension on the rocker arm, thereby easing the installation of the pump.

Clutch and Transmission Section

NOTE: 1969 linkage adjustment information is in this section. Repair procedures on both automatic and manual shift transmissions are covered elsewhere in this manual. Procedures for removing automatic transmissions as well as linkage adjustments on 1963-68 models are included in the automatic transmission chapters. See Chapter Index.

CLUTCH PEDAL, ADJUST

NOTE: See below for models equipped with the "E-Stick" Clutch and Shifting mechanism.

In order to provide sufficient free movement of the clutch release bearing when the clutch is engaged and pedal fully released, free pedal play should be 7/8" to 1 1/8" with 1" desired.

Adjustment for free pedal play is made by varying the length of the beam or link to the release lever rod. Lengthening this rod reduces pedal travel; shortening it increases pedal play.

CLUTCH, REPLACE

Removal

Disconnect the release fork pull-back spring and remove the clevis pin from the end of the release fork rod. Disconnect the release fork at the pivot and pull the fork out as far as possible. Remove the transmission as described under *Transmission, Remove & Replace.*

Remove the clutch housing pan and mark the clutch cover and flywheel so that the clutch may be installed in the same relative position. Loosen the clutch cover bolts gradually and evenly until the clutch spring pressure is entirely relieved. Remove the bolts, and the clutch assembly may be removed from below.

Unless special clutch rebuilding equipment is available, it is recommended that the clutch assembly be exchanged for a rebuilt unit should the clutch require rebuilding. The driven disc, however, may be replaced without special equipment. If clutch rebuilding equipment is available, follow the equipment manufacturer's instructions.

SERVICE BULLETIN

Lubricates Clutch Cover: Three felt pads in the clutch cover are lubricated in production before they are assembled over the eyebolts. A squeak that may oc-

Fig. 1 "E-Stick" clutch control components. 1963-64

Fig. 2 "E-Stick" electrical circuits

cur during clutch operation after mileage has accumulated can be eliminated by relubricating the felt pads.

To do this, remove the cover pan from the clutch housing. Next, with a squirt-type oil can, carefully apply a mixture of heavy oil and mineral spirits to the three felt pads. Use only a small amount of lubricant, and make certain the lubricant does not get on the clutch driven member. Then apply a thin coating of a suitable light grease to the sides of the pressure plate lugs, where the lugs extend through the clutch cover. Install the pan to complete the job.

Clutch, Install

1. Very sparingly apply front wheel bearing lubricant to the clutch shaft pilot bearing in the crankshaft. If too much lubricant is used, it will run out of face of flywheel when hot and ruin driven plate facings. Make certain that flywheel surface is clean and dry.
2. Make sure that splines in driven plate hub are clean, and apply a light coating of lubriplate. Driven plate facings must be clean and dry.
3. Place driven plate on pressure plate, then place clutch assembly in position on flywheel, being sure to align marks made on flywheel and cover before removal.
4. Install cover bolts with washers but do not tighten.
5. Insert a spare clutch shaft through hub of driven plate and into pilot bearing.
6. Tighten each clutch cover bolt several turns at a time to draw cover evenly to flywheel and avoid distortion of cover.
7. While tightening cover bolts, move clutch shaft from side to side to center driven plate with pilot bearing. If driven plate is not centered, it will be difficult to slide the transmission into place. Make sure all cover bolts are uniformly tightened.
8. Remove aligning clutch shaft and install transmission, clutch linkage and adjust clutch pedal free play.

NOTE

On models with "E-Stick" clutch, before removing the aligning tool, pull out the Tow Start Control Handle and lock into position by turning the handle ¼ turn clockwise.

"E-STICK" CLUTCH, 1963-64

Description

The clutch used with the "E-Stick" operating components is similar to the conventional clutch but the necessity of operating the clutch physically when starting or shifting gears is eliminated.

In addition to the hydraulically operated release lever, the basic difference in the operation of conventional and E-Stick clutches is that the release bearing with the E-Stick clutch *engages* the clutch as it presses against the levers on the pressure plate. Also, the springs normally used in a pressure plate assembly have been omitted, and the release bearing rides continually on the pressure plate levers while the clutch is engaged.

The clutch is disengaged until the servo is applied by oil pressure when the shift lever is placed in gear position with the engine running. Once the lever is shifted into a gear position, (engine idling) a minimum pressure of 7 psi is maintained in the servo and control valve body to keep the clutch partially engaged, thereby eliminating drive line backlash. As the engine speed increases, oil pressure increases and the clutch becomes fully engaged.

The hydraulic pressure required to operate the clutch is supplied by the engine oil pump. The control valve body, Fig. 1, which also serves as the engine oil pump cover, governs the oil supply to the servo piston in accordance with the shift lever position, engine speed and manifold vacuum. The servo piston in turn actuates the release and engaging fork and bearing in response to driving requirements.

To assist in maintaining a fine control over clutch operation, two spring-loaded vacuum controlled diaphragms are connected in series to control the spring load on the regulator valve.

The air valve solenoid, controlling the dump diaphragm, is energized by an actuator cam and switch assembly mounted on the steering column inner and outer tubes, respectively. The actuator cam and switch assembly, with the shift lever in neutral and during gear changes, connects the dump diaphragm to manifold vacuum. With vacuum acting on the dump diaphragm, spring load is taken up which allows the pressure regulator valve to move off its seat, causing zero pressure in the servo and disengagement of the clutch. At all other times the dump diaphragm is connected to the atmosphere, giving the control valve a potential pressure of 17 psi.

Fig. 3 Clutch throw-out bearing and lever assembly

"E-STICK" TESTS & ADJUSTMENTS

Stall Test

1. Operate engine for about 30 minutes to bring oil and water temperatures to normal operating range.
2. Mount a tachometer in such a manner so as to be visible from the driver's seat.
3. If possible drive car on level ground in high gear at 10 mph. Move throttle to wide open position. Put light pressure on brake pedal to maintain 10 mph and note rpm indicated on tachometer; this should be 975 to 1125 maximum.
4. If impossible to drive car as above, set park brake and move shift lever into high gear.
5. Set foot brake and open throttle fully by depressing accelerator pedal to floor. Engine speed should settle out between 975 and 1125 rpm. *Caution: Do not hold throttle open for more than two seconds as severe damage to the clutch assembly will result. And do not repeat the stall test for at least one-half hour.*
6. If the stall rpm checks too high, refer to the *Trouble Shooting* chapter for likely causes of excessive slippage. If rpm is too low, the engine is not developing full power.

Oil Pressure Test

1. This test will indicate whether the valve and diaphragm are functioning properly. Operate engine for about 30 minutes to bring oil and water temperatures to normal operating range.
2. Install a pressure gauge at one of the pipe plug provisions on the engine oil gallery.
3. Remove vacuum hose at intake manifold fitting and plug manifold opening. *Do not plug loose end of hose.*
4. Mount a tachometer. Then with shift lever in neutral, oil pressure should be 27 to 32 psi at 1100 rpm. *Engines that contain original factory installed engine oil will show pressures about 3 to 4 psi less than pressure specifications above.*
5. If oil pressure is not within proper limits, inspect the pressure regulator valve to be sure that its cap is in place and not plugged; the valve must also move freely in the valve body bore. Check the valve body-to-oil pump gasket thickness; should be .011-.013". If the foregoing are not the cause of the trouble, replace engine oil pump and valve body and diaphragm assembly.

Clutch Release Lever, Adjust 1963-64

This adjustment is only necessary when a new clutch disc is installed. Before attempting to make the adjustment, make certain that the servo piston, Fig. 1, is all the way forward in the servo bore (toward front of car).

1. Turn release lever adjusting screw to make light contact with piston rod. Then back off adjusting screw two turns and tighten lock nut.
2. Loosen lock nut on tow start cable. Adjust tow start hex adjuster, so that the pivot clears the release lever by ⅛" and tighten lock nut.

Servo Self-Adjuster, 1963-64

The servo self-adjuster, Fig. 1, contains a nylon washer and two Belleville washers. These items are contained within the unit and are only serviced as a complete assembly.

The self-adjuster has the three washers installed on a guide pin. When the assembly is pressed on the servo piston rod, the guide pin is released from the assembly as soon as the three washers are positioned on the piston rod. The two Belleville washers control piston rod travel so contact with the clutch release is not lost.

Shift Mechanism, Adjust

1. Loosen trunnion locknut from low-reverse gearshift rod. Disconnect shift rods from transmission lever trunnions.
2. Install a ¼" aligning pin in holes of operating levers at steering post, indexing pin in groove of lever spacer. This is the neutral position of operating levers.

Fig. 5 Self-adjuster

Fig. 4 Main lever bracket assembly

3. With aligning pin in position and transmission shift levers in neutral, adjust trunnions on gearshift rods so that trunnions enter transmission levers freely.
4. Reassemble gearshift rods into transmission levers, tighten locknuts and remove aligning pin.

Actuator Cam Switch, Adjust

The actuator cam switch controls the release of the clutch simultaneously to shifting gears. The switch mounting bracket has slotted holes to permit adjustment of the switch.

When the shift lever is moved out of second or high gear, the switch will emit a slight "click", closing the switch circuit, thereby releasing the clutch. There must be an equal amount of lever movement coming out of second or high gear before the switch clicks. Adjust switch bracket to meet these conditions. Fig. 2 shows the "E-Stick" electrical circuits.

Actuator Cam Stop, Adjust

With the shift lever in high gear, adjust the cam stop to take up approximately ½ of the lever free movement. This will center the slot in the second and high operating lever over the selector key, removing any tension between the two.

SELF-ADJUSTING CLUTCH

Clutch Removal

Clutch removal requires prior removal of the main spring, main lever assembly and the clutch housing. Always index mark the clutch cover assembly and flywheel on original production assemblies before removal so these parts can be assembled in the same relative position.

NOTE: When necessary to replace the clutch driven plate after accumulated mileage, a new self-adjuster link must also be installed.

Fig. 6 Cable adjustment

Fig. 7 Aligning pin used when adjusting Ainsworth type shift mechanism. 1963-66

Clutch Installation

1. Bolt cover to flywheel. Install rubber dust shield on opening in clutch housing.
2. Position throw-out bearing and lever assembly with strut in clutch housing. Lubricate strut seat in throw-out lever with engine oil. Secure throw-out lever assembly with retaining spring, Fig. 3.
3. Secure clutch housing to engine with main lever and bracket assembly in proper position, Fig. 4. Tighten upper bracket bolt to 40-45 ft-lbs and lower bolt 35-40 ft lbs.
4. Place lower end of cable in mounting hole in main bracket. Place cable and fitting over pin on bellcrank and secure in place.
5. Install self-adjuster on the headed pin on bellcrank and insert threaded end of self-adjuster with flat washer and seal in socket on end of throw-out lever, Fig. 5.
6. When in proper position, wire extension on threaded portion of self-adjuster will be in opening of actuator. Remove instruction tape from self-adjuster.
7. Use a suitable clutch aligner to position clutch driven plate.
8. Install main spring, Fig. 4.
9. Remove aligning tool and install transmission.
10. Install cable adjuster gauge on main bracket, Fig. 6.
11. With clutch pedal secured in extended position on toeboard, adjust cable to obtain a snug fit on cable adjuster gauge by adjusting the upper cable retaining nut. After this adjustment is made, secure cable in position with the lower cable retaining lock nut and remove gauge.

NOTE: Operate clutch pedal in normal manner until automatic self-adjuster reaches normal operating position. This position is reached when the wire extension, being actuated by clutch pedal movement, has extended the threaded portion of the self-adjuster rearward until the wire does not contact the opening of the actuator. This will require 10 to 20 strokes of the pedal. No clutch pedal free play will be present as the fingers of the clutch cover are in contact with the face of the throw-out bearing at all times.

MANUAL TRANS.

Three Speed, Replace

1969

1. Raise car and support engine.
2. Mark rear U-joint yoke to aid in assembly, and disconnect propeller shaft from rear axle.
3. Slide front U-joint from transmission mainshaft.
4. Remove screws from rear engine support cushion at extension housing.
5. Remove bolts that secure rear crossmember to sills and remove crossmember.

NOTE: Before removing rear member on Javelin and AMX with power steering, open hood to avoid damage from pump reservoir wing nut.

6. Disconnect speedometer cable and shift rods from transmission.
7. On Javelin models with floor shift, remove shift lever bezel, boot, retainer and shift lever.
8. When removing transmission, use guide pins in place of two lower cap screws so as not to damage clutch shaft.

1967 American & 1968 All Models

1. Jack up or support engine.
2. Unfasten rear engine support cushion from extension housing (2 capscrews).
3. Unfasten and remove rear crossmember. *An additional body crossmember is used on Convertible models. Therefore, it is also necessary to remove crossmember tie plate* when removing transmission.
4. Remove propeller shaft.
5. Disconnect speedometer cable and gearshift rods from transmission levers.
6. Unfasten and remove transmission.
7. Reverse procedure to install.

1967 Rambler

1. Unfasten and remove exhaust pipes from exhaust manifolds.
2. Remove propeller shaft.
3. Jack up or support engine.
4. Unfasten rear engine support cushion from extension housing (2 capscrews).
5. Unfasten and remove crossmember.
6. Disconnect speedometer cable and gearshift rods from transmission levers.
7. Unfasten and remove transmission.
8. Reverse procedure to install.

1965-66 American

1. Jack up or support engine.
2. Unfasten rear engine support cushion from extension housing or torque tube adapter (2 capscrews). *On Convertible models, an additional crossmember is used; therefore, it is also necessary to remove crossmember tie plate when removing transmission.*
3. On 6-199 engine, raise and support rear of body at side sills. Disconnect rear shocks at rear axle tubes, hand brake cable at adjusting yoke, and rear brake hose clip from body floor pan. Remove rear spring U-bolts and move rear axle to rear and remove front U-joint from transmission mainshaft.

   On 6-232 engine, remove propeller shaft by separating rear U-joint and sliding front U-joint from transmission mainshaft.
4. On all models, disconnect speedometer cable and gearshift rods from transmission levers.
5. Unfasten and remove transmission.
6. Reverse procedure to install.

1963-66 Rambler

1. On V8s, unfasten exhaust pipes from exhaust manifolds.
2. Jack up or support engine.
3. Unfasten rear engine support cushion from extension housing or torque tube adapter (2 capscrews).
4. Unfasten and remove crossmember.
5. Lower jack supporting engine so ex-

tension housing or torque tube adapter clears reinforcing rib in floor pan.
6. Disconnect brake tube bracket from underside of body.
7. Disconnect shock absorbers at lower bracket. Then disconnect torque tube at rear of transmission extension housing.
8. Disconnect parking brake cable at equalizer and brake cable housing at torque tube bracket.
9. Move rear axle rearward to remove front U-joint from transmission mainshaft.
10. Disconnect speedometer cable and gearshift rods from transmission levers.
11. Unfasten and remove transmission.
12. Reverse procedure to install.

1963-64 American

1. Jack up or support engine.
2. Remove two capscrews from rear engine support cushion at torque tube adapter.
3. Raise and support rear of body at side sills.
4. Support rear axle at center of housing.
5. Disconnect rear shock absorbers at rear axle tubes, hand brake cable at adjusting yoke, and rear brake hose clip at body floor pan.
6. Remove rear spring front bracket attaching nuts and lower rear axle, continuing to support body, thus lowering rear spring front brackets from floor pan.
7. Move rear axle rearward to remove front U-joint from transmission mainshaft.
8. Disconnect speedometer cable and gearshift rods from transmission shift levers.
9. Unfasten and remove transmission.
10. Reverse procedure to install.

Four Speed, Replace

1966-67 & 1969 All Models

1. Remove chrome trim ring that secures rubber boot to floor pan and slide boot up on shift lever.
2. Unfasten and remove shift lever from cross shaft (2 capscrews).
3. Raise vehicle.
4. Unfasten and remove exhaust pipes from exhaust manifolds.
5. Jack up or support engine.

Fig. 9 Aligning shift bowl. 1967 gearshift

Fig. 8 Aligning pin used when adjusting Douglas type shift mechanism. 1963-64

6. Unfasten rear engine support cushion from crossmember.
7. Unfasten and remove crossmember.

NOTE: Before removing crossmember on Javelin and AMX models with power steering, open hood to avoid damage from pump reservoir wing nut.

---

8. Remove propeller shaft.
9. Disconnect speedometer cable from transmission.
10. Lower engine until adequate clearance is obtained to permit transmission removal.
11. Reverse procedure to install.

1968 All Models

The procedure to remove the transmission is the same as that given previously for the three speed transmission.

MANUAL TRANS. SHIFT LINKAGE

1968-69 Three Speed

1. Loosen the trunnion lock nuts on the gear shift rods.
2. Position the two operating levers in the center of the jacket tube cutout.
3. Insert a $\frac{3}{16}$" drill bit through the aligning holes of the two shift levers, shift gate and the bracket on the jacket tube.
4. With the shift levers in the neutral position, carefully adjust the trunnions to a free fit in the shift levers and secure the trunnion in this position with the lock nuts. Use care when tightening the lock nuts so a binding condition does not exist.

1967 Three Speed

1. Place shift levers on transmission in neutral.
2. Loosen all shift rod trunnion lock nuts about four turns.
3. Align center-line of column gearshift lever with center-line of hazard warning light switch knob.
4. Place a 2" piece of masking tape along top edge of shift bowl adjacent to the gap between the shift bowl and the turn signal switch cover.
5. Place a second piece of tape along the lower edge of the turn signal switch cover and directly across the gap from the first tape. Draw a line across both pieces of tape, Fig. 9.
6. Measure ⅝" to the right of the line on the shift bowl tape and draw another line as shown.
7. Raise the shift lever to align the ⅝" line on the shift bowl tape with the index line on the stationery tape. This is the proper neutral position.
8. Hold the shift bowl in this position by taping the bowl to the switch housing, Fig. 10.
9. With the shift levers and transmission levers in the proper neutral position, adjust the trunnions to a free fit in the levers while holding the low-reverse lever aligned with the second-high lever. When tightening the lock nuts, maintain proper trunnion alignment to prevent binding.
10. Remove tape and check shifting operation in all gears.

1968-69 Four Speed

1. Loosen the transmission shift lever nuts (two on each lever) and loosen the lock nuts on the reverse shift rod at the trunnion.
2. Install a ¼" drill bit through the selector lever retainer, through the levers, spacer plate, and through the aligning hole in the mounting bracket.
3. This is the neutral position. Place all three transmission levers in the neutral position.
4. Adjust the trunnion on the reverse shift rod to enter freely into the reverse lever. Lock the check nuts on the reverse rod and secure with washer and cotter pin.
5. Tighten the lower nuts of the shift levers first, being careful not to move the outer levers out of position.
6. Tighten the upper "hug nuts" to 10 ft. lbs. Do not overtighten or the shift shafts could be broken. Remove the aligning pin.

1966-67 Four Speed

1. Loosen transmission shift lever nuts (2 for each lever) and remove trunnion from reverse shift lever.
2. Remove access cover from left side of console.

Fig. 10 Locating neutral position of shift bowl. 1967 gearshift

3. Install a $\frac{5}{16}$" drill bit through selector lever retainer, through the levers, spacer plate and through the aligning hole in shift lever pivot bracket. This is neutral position for the three selector levers.
4. Place all three transmission levers in neutral. Adjust trunnion on inner reverse shift rod to enter freely into reverse lever. Lock check nut on reverse rod and secure with washers and cotter pins.
5. The outer levers on transmission side cover plate will be in proper position as the two nuts were loose when the aligning pin was installed. Tighten lower nuts first, being careful not to move outer levers out of position. Then torque upper "hug" nuts to 8-10 ft-lbs. Do not over-torque these nuts as the shift shafts could be broken.
6. Remove aligning pin and check shift operation in all positions.

1963-66 Three Speed (Ainsworth Type)

1. Loosen trunnion lock nuts on shift rods.
2. Use a $\frac{3}{16}$" diameter rod as an aligning pin. Insert pin as shown in Fig. 7. This is neutral position of operating levers.
3. Adjust trunnions on shift rods so they enter freely into operating levers while transmission shift levers are in neutral position.
4. Tighten trunnion lock nuts and remove aligning pin.

1963-64 Douglas Type

1. Loosen trunnion lock nuts on shift rods.
2. Insert a ¼" pin as shown in Fig. 8. This is neutral position of operating levers.
3. Adjust trunnions on shift rods so they enter freely into operating levers while transmission levers are in neutral position.
4. Tighten trunnion lock nuts and remove aligning pin.

1969 AUTO. TRANS. LINKAGE ADJUST

1. With transmission lever in "N" position, pull shift rod against shifter gate.
2. Push selector lever forward to remove any free play and adjust the clevis for a free pin fit in the transmission outer lever.

All other adjustments are the same as for 1968 models and can be found in the front section of this manual.

Rear Axle, Propeller Shaft & Brakes

REAR AXLES

Fig. 1 illustrates the rear axle assembly used on these cars. When necessary to overhaul the unit, refer to the *Rear Axle Specifications* table in this chapter

Description

In these rear axles, Fig. 1, the drive pinion is mounted in two tapered roller bearings. These bearings are preloaded by a washer behind the front bearing. The pinion is positioned by shims located in front of the rear bearing. The differential is supported in the carrier by two tapered roller side bearings. These bearings are preloaded by shims located between the bearings and carrier housing. The differential assembly is positioned for proper ring gear and pinion backlash by varying the position of these shims. The differential case houses two side gears in mesh with two pinions mounted on a pinion shaft which is held in place by a lock pin. The side gears and pinions are backed by thrust washers.

Since the axle tubes are pressed into the differential carrier to form a one-piece housing, major service work requires the removal of the rear axle assembly from the car, the procedure for which follows:

Fig. 1 Rear axle assembly. For 1967-69 V8s the pinion bearing preload is adjusted by means of a collapsible spacer instead of the shim shown

REAR AXLE & PROP. SHAFT, REPLACE

1968 American, AMX & Javelin; 1969 Rambler, AMX & Javelin

1. Remove axle shaft nuts prior to raising the car weight from the wheels.
2. Remove the axle housing cover to drain the lubricant.
3. Raise and support the rear of the body.
4. Remove the rear wheels and rear wheel hubs and drums.
5. Disconnect rear parking brake cables at equalizer.
6. Remove the brake support plates.

NOTE: Retain the shims located between the left support plate and axle tube for use on reassembly.

7. Remove the axle shafts from the axle.
8. Mark the universal joint yoke and bearing before separating to insure same alignment at time of assembly. Disconnect the propeller shaft at the rear universal joint.
9. Disconnect the rear shocks at the axle.
10. Disconnect the brake line at the body floor pan bracket.
11. Remove the rear spring U bolts and the axle may now be removed.

1968-69 Rebel & Ambassador

1. Remove axle shaft nuts prior to raising the car weight from the wheels.
2. Raise and support the rear of the car.
3. Remove the axle housing cover and drain the lubricant.
4. Mark the rear universal joint and

Fig. 2 Loosening propeller shaft coupling. 1963-66 American with 6-196, 199 engines

Fig. 3 Correct propeller shaft coupling location. 1963-66 American with 6-196, 199 engines

bearing and disconnect the propeller shaft at the rear universal joint.

5. Disconnect the parking brake cable at the equalizer.

NOTE: The left cable is routed to upper long end of equalizer. Disconnect the brake lines at the support plates.

---

6. Remove the wheels, hubs, drums, support plates, seals, axle shafts and bearings.
7. Support the axle assembly and disconnect the shocks at the axle tubes.
8. Lower axle assembly until it is supported by the control arms.
9. Pull one axle tube down and remove the spring. Pull the other axle tube and remove the other spring.
10. Support the axle assembly and disconnect the upper control arms at the axle housing.
11. Disconnect the lower control arms at the axle tubes and the axle may now be removed.

1963-66 American

1. To remove, first raise and support rear of body.
2. Disconnect and remove hand brake cables from brake assemblies.
3. On cars with 196 and 199 engines, use the type wrenches shown in Fig. 2 to remove the propeller shaft. The coupling nut dust shield will serve as a puller to partially remove the propeller shaft from the rear axle pinion.
4. On cars with 6-232 engine the propeller shaft is removed by separating the rear universal joint by removing the two U-bolts. The drive pinion yoke is removed by removing the cap screw that holds the yoke to the pinion shaft.
5. Disconnect rear shock absorbers, rear brake line at bracket on body floor pan and rear springs from body.
6. Move axle and springs back far enough to permit the propeller shaft to be slipped out of the front universal joint.
7. Separate axle from springs and slide axle back and out from under car.

NOTE: On cars with 196 and 199 engines, install the propeller shaft and coupling on the rear axle pinion shaft until the center of the universal joint yoke is positioned as shown in Fig. 3, measured from the front face of the rear axle housing.

1963-67 Rambler & 1967 American

1. To remove propeller shaft, first raise and support rear of body.
2. Disconnect parking brake cable at equalizer and parking brake cable housing at torque tube bracket.
3. Disconnect torque tube from transmission, rear brake hose at bracket on body floor pan, shock absorbers at shock mounting bracket, and stabilizer bar at axle tube. The rear springs are held in position in spring seats by car weight and shock absorber travel limits.
4. Roll axle free from car and disconnect truss rods, torque tube and propeller shaft from rear axle.

NOTE: A "slip" or "union" type coupling is used, Fig. 4. On cars with 6-199 engine with standard and automatic transmission, and 6-232 engine with automatic transmission incorporate a vibration damper as part of the slip-type propeller shaft coupling assembly. The propeller shaft and coupling can be slipped off the pinion shaft when disconnecting the propeller shaft and rear axle.

SERVICE BULLETIN

Licks Pinion Leak: Incorrect reinstallation of a propeller shaft and torque-tube assembly can cause a leakage of rear axle lubricant past the pinion oil seal.

A correct positioning of the propeller shaft coupling on the rear axle pinion shaft must be made when the torque tube and propeller shaft are assembled to the rear axle housing. This will assure proper contact of the pinion oil seal with the seal area of the slip-type coupling for the propeller shaft.

To check for proper positioning of the coupling, measure from the flange of the torque tube trunnion to the forward edge of the universal joint yoke. This dimension should be 4 1/16 in. for 1963-66 Classic 6 cyl. cars and 6 in. on 1963-66 Classic and Marlin V8's and 1963-66 Ambassadors.

Fig. 4 Slip-type propeller shaft coupling. Classic, Marlin and Ambassador

Fig. 5 Arrows indicate where to measure for correct positioning of propeller shaft coupling on rear axle pinion shaft. Marlin, Classic and Ambassador

Fig. 5A Installing hub on axle shaft

AXLE SHAFTS

The hub and drum are separate units. The drum is attached to the hub by cap screws on V8s and by speed nuts on sixes. Also, the hub and axle shaft are serrated to mate and fit together on the

Fig. 6 Bendix Duo-Servo Brake. Left view is a left front brake. Right view is a right rear brake

Fig. 7 Wagner Compound Shoe-Type Brake. Left view is a left front brake. Right view is a right rear brake

taper. Both are punch marked to insure correct assembly, Fig. 5A. The axle shaft is removed as follows:

1. Remove the wheel and then remove the brake drum which is retained by cap screws on V8s and speed clips on Sixes.
2. Remove the hub with a suitable puller. *Do not use a knock-out type puller as damage to the wheel bearings or thrust block may result.*
3. Remove brake support plate, oil seal and shims.
4. Remove axle shaft with a puller.

NOTE

Do not use an original hub on a replacement axle shaft; use a new hub. A new hub may be installed on an original axle shaft providing the serrations on the shaft are not worn or damaged. Be certain that the hub and axle shaft are punch marked to insure proper alignment on installation. A replacement hub, which is not serrated, can be installed and serrations will be cut in the hub when installed on the shaft due to the difference in hardness of the shaft and the hub.

When installing the hub onto the axle shaft tighten the axle nut to 150-200 lbs. ft. A measurement of $\frac{3}{16}$" should exist between the face of the hub and the outer taper of the axle shaft, Fig. 5A.

Assembly

Replace the parts in the reverse order of their removal. If the old parts are replaced and the shims have not been disturbed, the axle shaft end play should be correct when the parts are assembled. However, if a new shaft, bearing, differential carrier or housing has been installed, it will be necessary to check the end play.

The end play can be checked when all parts have been replaced except the wheel and hub. To make this check, rap each axle shaft after the nuts are tight to be sure the bearing cups are seated. Then place a dial indicator so that its stem contacts the end of the shaft and work the shaft in and out to determine the amount of existing end play. If an adjustment is necessary, remove the outer oil seal and brake support and add or remove shims as required. When making this adjustment, an equal thickness of shims should be removed or added on each side of the axle housing to maintain a central position of the differential thrust block.

NOTE

The application of a bead of sealing material such as "Pliobond" or "Permatex" to the outer diameter of axle tube flange and the brake support contact area is recommended. The sealing material will be used in addition to the gasket for improved sealing.

BRAKE ADJUSTMENTS

SERVICE BULLETIN

To Stop Brake Squeal: A brake squeal which may occur on a Classic or Ambassador V-8 having 10 in. Bendix Duo-Servo type brakes with bonded lining is usually confined to the front wheels. The noise can be eliminated by installing heavier hold-down springs on the front shoes, and a drum spring on the front drums.

To make the correction, remove the black-colored springs which hold the brake shoes to the support plates, and replace them with heavier springs available for the purpose.

A simple method of installing the springs on the drums, if a special tool is not available, is to cut the top off a tapered metal pail so that the cut edge just covers the outer edge of the drum. Place the pail on the drum, hook the spring ends together, and slip the spring over the narrow end of the pail. Then roll the spring over the pail and into position against the drum flange.

1963-69 Self-Adusting Brakes

These brakes, Figs. 6 and 7 have self-adjusting mechanisms that assure correct lining-to-drum clearances at all times. The automatic adjusters operate only when the brakes are applied as the car is moving rearward.

Although the brakes are self-adjusting, an initial adjustment is necessary after the brake shoes have been relined or replaced, or when the length of the star wheel adjusting screw has been changed during some other service operation.

Frequent usage of an automatic transmission forward range to halt reverse vehicle motion may prevent the automatic adjusters from functioning, thereby inducing low pedal heights. Should low pedal heights be encountered on these models, it is recommended that numerous forward and reverse stops be made until satisfactory pedal height is obtained.

NOTE

If a low pedal condition cannot be corrected by making numerous stops (provided the hydraulic system is free of air) it indicates that the self-adjusting mechanism is not functioning. Therefore, it will be necessary to remove the brake drum, clean, free up and lubricate the adjusting mechanisms. Then adjust the brakes as follows, being sure the parking brake is fully released.

Adjustment

1. When the brake parts have been installed in their correct position, initially adjust the star wheel assemblies to a point where $\frac{3}{16}$" to ¼" of threads are exposed between star wheel and star wheel nut on Series 10, ⅜" of threads exposed on American, Ambassador and Rebel models.
2. Following the initial adjustment and final assembly, check the brake pedal height to insure brake operation. Then drive the car forward and reverse, making 10 to 15 brake applications prior to road testing. This action balances the adjustment of the four brake units and raises the brake pedal.

PARKING BRAKE, ADJUST

1968 American; 1969 Rambler

1. With service brakes properly adjusted, pull parking brake handle to the third notch from the released position.
2. Tighten the parking brake cable at the equalizer to a point where the rear wheels are locked from forward rotation.
3. Release brake handle and check for rear brake drag—wheels should rotate freely.

1963-67 Rambler; 1968 Except American; 1969 Except Rambler

1. With service brakes properly adjusted, set parking brake pedal on the first notch from fully released position.
2. Tighten parking brake cable at equalizer to a point where the rear wheels are locked in forward rotation.
3. Release pedal and check for rear wheel drag—wheels should rotate freely.

1963-67 American

1. With service brakes properly adjusted, pull parking brake handle to fifth notch from fully released position.
2. Tighten parking brake cable at equalizer to a point where the rear wheels are locked in forward rotation.
3. Release brake handle and check for rear brake drag—wheels should rotate freely.

BRAKE MASTER CYLINDER, REPLACE

To remove the master cylinder, disconnect the brake lines from the connections on the master cylinder. Unfasten the cylinder from its mounting and remove from the car.

Install in the reverse order of removal and bleed the brake system.

Front End and Steering Section

FRONT SUSPENSION

The front suspension, Fig. 1, is an independent link type. The right and left assemblies may be disassembled on the car or removed for bench overhaul.

The coil springs are located between the upper seats of the steering knuckle pins and a seat in the wheelhouse panel. Transmission of road noise through the springs is minimized by insulating the springs from the body with rubber cushions.

The shock absorbers are the direct-acting type with built-in rebound bumper control. The end mountings of the shocks are retained in rubber grommets.

The upper control arms contain rubber insulated bushings installed in the inner end of the arms. The control arms are attached to the mounting bracket on the wheelhouse panel and the trunnion at the outer end.

The lower control arms are attached to a removable crossmember at the pivot ends. The outer ends are attached to the steering knuckle pin with a ball joint stud.

LUBRICATION

Rambler 1963-68 models and American 1964-68 are equipped with plugs which must be removed and a hand-operated grease gun used with special grease to lubricate the suspension at 32,000-mile intervals or three years, whichever occurs first under normal driving conditions.

Under severe driving conditions, such as dusty or extreme wet conditions, earlier lubrication is recommended. Under these conditions the suspension system should be inspected every 12,000 miles or one year whichever occurs first, and lubricated as required.

WHEEL ALIGNMENT

1964-67 American & 1968-69 All

Caster is obtained by moving the two adjusting nuts on the threaded strut rod, Fig. 2. One nut is on each side of the mounting bracket. Therefore, moving the nuts on the rod will move the lower control arm to front or rear for desired caster angle. After adjustment, torque nuts to 85 ft-lbs.

Camber is obtained by turning on the eccentric lower control arm bolt, Fig. 2.

Fig. 1 Front suspension (typical)

Fig. 2 Front suspension (rear view) showing caster and camber adjustments. 1964-67 American & 1968-69 All

After adjustment, torque lock nut to 95 ft-lbs.

1963 American

As shown in Fig. 3, U-shaped spacers are installed between the lower control arm pivot bar and mounting surface. Increasing or decreasing the number or thickness of the "U" spacers at either the front or rear mounting bolt permits adjusting the caster angle.

Increasing or decreasing equally at both the front and rear mounting bolts will change camber angle.

Fig. 3 Caster and camber adjusting shim location. 1963 American

NOTE: The lower control arm pivot bar brace must be loosened prior to making caster and camber adjustments. When installing the brace, torque attaching bolts to 70-80 ft-lbs.

1963-67 Rambler

The upper control arm attaching bolts are provided with eccentric washers, one attached to the bolt and the other keyed to the threaded end of the bolt.

Loosening the attaching bolt nuts will permit turning the bolt and the eccentrics to provide caster and camber adjustment. Tool J-9447, Fig. 4, which is a special ⅞" box ratchet wrench, may be used on the eccentric bolts and nuts with a combination ⅞" open end and box wrench.

After adjustment, the eccentric bolt nuts should be tightened 50-55 ft-lbs torque. A torque limiting type wrench should be used to measure the torque effort accurately.

TOE-IN, ADJUST

To adjust toe-in, loosen the clamps at both ends of the adjustable tubes on each tie rod. Turn the tubes an equal amount until the toe-in is correct. Turning the right tube in the direction the wheels revolve when the car is going forward increases the toe-in and turning the left tube in the opposite direction increases toe-in. To decrease toe-in turn the right tube backward and the left tube forward. It is important that both tubes be turned an equal amount in order to maintain the correct position of the steering wheel. When adjustment is complete, tighten all clamp bolts.

NOTE

In performing service operations on the steering linkage or when adjusting toe-in, be sure to square the tie rod ball sockets on the studs and align the tie rod stud in the center, or slightly above center, of the cross tube opening, before tightening the steering linkage adjusting tube. This will prevent the stud from

Fig. 4 Caster and camber eccentric adjusting tool. 1963-67 Rambler

Fig. 6 Front wheel bearing adjustment. 1965-67

contacting the side of the cross tube opening, which would otherwise result in noise problems or damage.

WHEEL BEARINGS, ADJUST

1968-69

1. To adjust bearings, tighten spindle nut to 20 ft-lbs torque while rotating the wheel to seat bearings.
2. Then loosen spindle nut ⅓ turn and with the wheel rotating retorque the spindle nut to 12 inch pounds.
3. Place the nut retainer on spindle nut with the slots of the retainer aligned with the cotter pin hole on the spindle.
4. Install cotter pin and dust cap.

1965-67

1. To adjust bearings, tighten spindle nut to 20 ft-lbs torque while rotating hub to seat bearings, Fig. 6.
2. Place nut retainer on adjusting nut so tabs of retainer cover cotter pin hole in spindle.
3. Back off adjusting nut and nut retainer together to the second slot. This will provide the desired .001″ to .006″ end play.
4. Install cotter pin and dust cap.

NOTE: To check end play, install a dial indicator on wheel hub or stud and set the sensing tip of indicator against spindle. An alternate method is to mount the indicator on the spindle nut and sensing tip against face of hub. Grasp tire and gently push and then pull outward. The end play will register on dial.

1963-64

1. To adjust wheel bearings, tighten spindle nut to 20-25 ft-lbs while rotating hub to seat bearings.
2. Back off nut 1/6 turn and install a cotter pin in aligned hole of spindle and castellation of adjusting nut. This should produce an end play of .001″ to .010″. Check end play with dial indicator as outlined above.

WHEEL BEARINGS, REPLACE

(Disc Brakes)

1. Remove two thirds of the total fluid capacity of the master cylinder reservoir to prevent fluid overflow when the caliper pistons are pushed back on their bores.
2. Raise car and remove front wheels.
3. Disconnect hydraulic tube from mounting bracket. Do not disconnect any hydraulic fitting.
4. Holding the lower edge of the caliper, remove the lower bolt. Any shims that fall out at this point should be labeled to insure that they be replaced in their original position.
5. Holding the upper edge of the caliper, remove the upper bolt, tag these shims.
6. Hang caliper from upper suspension to prevent strain being placed on brake hose.
7. Remove spindle nut and hub and disc assembly. Grease retainer and inner bearing can now be removed.

CHECKING BALL JOINTS FOR WEAR

1963-69

Before checking ball joints for wear, make sure the front wheel bearings are properly adjusted and that the control arms are tight.

Referring to Fig. 7, raise wheel with a jack placed under the frame as shown.

Fig. 7 Checking ball joints for wear. 1963-69

Then test by moving the wheel up and down to check axial play, and rocking it at the top and bottom to measure radial play.

Lower ball joint should be replaced if there is any noticeable looseness at the joint (no upper joints used).

BALL JOINT, REPLACE

1. Drill out the two rivets that attach ball joint to lower control arm.
2. Remove two strut rod mounting bolts.
3. Remove steering knuckle arm and stud nut and remove ball joint from knuckle pin with a suitable ball joint remover.
4. When installing new ball joints, note that two bolts, lockwashers and nuts are furnished to replace rivets that were removed.

SHOCK ABSORBER, REPLACE

After disconnecting the shock from the wheelhouse panel at the top and from the lower control arm at the bottom, collapse the unit, work to one side and remove from out of the lower control arm.

Reverse the foregoing procedure to install.

Fig. 8 Line up of steering wheel and shaft through to steering gear. 1965-66 American

SPRING, REPLACE

1963-69

1. To remove a spring, raise rear end of car opposite from side from which spring is to be removed. Additional pressure may be gained by leaning on fender over the spring.
2. Install hooks in holes on ears of spring seats. Hooks will hold spring in compressed position to allow removal from vehicle. A service spring may be installed as follows:
3. Install upper and lower cushions and upper and lower spring seats on spring. Align holes in ears of upper and lower spring seats.
4. Compress spring by suitable means (arbor press or hydraulic jack) and install hook on spring seats. Spring can then be installed on spring support.

CAUTION: Lip of lower spring seat must engage seat support to prevent spring from shifting during operation.

5. Hooks are released from spring seat by raising opposite near end of vehicle.

STEERING GEAR, REPLACE

1967-69 All Models

1. Remove flexible coupling bolts.
2. Remove pitman arm, using a suitable puller.
3. Remove mounting screws and lower steering gear from vehicle.

1963-66 Rambler

1. Disconnect battery.
2. Remove horn blowing ring by pressing down at center and turning counterclockwise.
3. Remove steering wheel with a suitable puller.
4. Remove jacket tube support plate screws. Loosen steering jacket tube bracket-to-instrument panel bolts.
5. Remove pitman arm with a suitable puller.
6. Unfasten steering gear from mounting plate (3 screws) and remove gear from below car.

1963-66 American

1. Remove steering wheel and pitman arm, using suitable pullers.
2. Loosen steering jacket tube at support plate and at instrument panel mounting bracket.
3. Unfasten steering gear and remove it from below the car.

NOTE: On some 1965-66 models, two flexible couplings are used in steering shaft assembly, Fig. 8.

POWER STEERING,

1964-69

Steering Gear, Replace

1. Disconnect pressure and return hoses from gear. Raise hoses above pump level to keep oil from draining out of pump.
2. On 1964-66, remove lower flange pinch bolt. On 1967-69, remove flexible coupling bolt nuts, noting the different nut sizes to insure correct assembly.
3. Remove pitman arm with a suitable puller.
4. Remove gear attaching bolts.
5. Slide lower shaft free of coupling flange, then remove gear.
6. Reverse procedure to install. On 1965-66 American models, after gear is installed, do not tighten mounting bolts until clearance between coupling hub and gear housing is checked; it must be a minimum of .040", Fig. 8.

LINKAGE POWER STEERING

On Car Adjustments

Adjustment of belt tension and bleeding of the system are the only two "on the car" adjustments which can be made.

Fig. 9 Power cylinder and mounting parts. 1963

Fig. 10 Power cylinder components. 1963

Bleeding Systems

To bleed the system, raise front wheels and run engine at idling speed until normal operating temperatures are obtained. Then accelerate the engine and turn front wheels to right and left several times until bubbles in reservoir disappear. *Do not hold wheels against stops.* Always recheck and replenish fluid in reservoir after bleeding.

Fluid Pressure Test

A fluid pressure test will show whether the pump or some other unit in the power steering system is causing trouble. Connect an oil pressure gauge in the main oil line at the control valve assembly. Start the engine and allow the oil to circulate for several minutes to warm the oil.

1. Turn the wheels against the curbing or other obstacle and hold tension on the wheel. The oil pressure should be as follows:

   1963 Roll type pump.....800-900

   1963 Slipper Type 850-950

2. Turn the wheel in the opposite direction and note the reading. If there is a variation between the left and right turns, internal leakage is evident. If the pressure is low, stop the engine and disconnect the gauge from the valve and cap the pressure line.
3. Restart the engine and note the reading. If the pump is operating properly the pressures will be as noted in Step 1. If the pressure is low the pump belt or fan belt may be slipping. With belt tension correct and there is low pressure, the trouble exists in the pump. *Do not run the last check for a period longer than is necessary to obtain a steady pressure reading.*

Power Cylinder Removal

1. Disconnect the oil hoses, the piston rod from the side sill bracket, and the tie rods from the cylinder and valve assembly.
2. Remove the pitman arm stud nut and roll pin, washer, cushions and spacers.
3. Remove the cylinder and valve assembly from the pitman arm stud. If necessary to overhaul power cylinder, refer to Figs. 9 and 10.

Power Cylinder, Install

1. Install the valve housing end of cylinder on the pitman arm.
2. Tighten the inner nut on the stud until there is sufficient tension on the rubber cushions to prevent rattles and grease leakage and still permit free movement of the stud. *Overtightening the stud will cause poor recovery from turns and binding when steering. Looseness may result in shimmy.*
3. When the stud nut is correctly adjusted, the locking roll pin should be installed.
4. After the cylinder has been installed in the car, and the hoses connected, fill the pump reservoir and bleed the system as outlined previously.

Control Valve

If necessary to adjust the valve spool assembly for correct centering, turn piston rod end plug *OUT* and turn pitman arm end plug *IN* the same amount about ½ turn at a time for the following conditions:

Left turn is to hard
Right turn is too easy
Poor recovery from right turns, but good recovery from left turns
Car wanders to the right

Turn pitman arm end plug *OUT* and piston rod end plug *IN* the same amount about ½ turn at a time for the following conditions:

Right turn is too hard
Left turn is too easy
Poor recovery from left turns, but good recovery from right turns
Car wanders to the left

After final adjustment, tighten end plugs securely to 50 ft. lbs.

Engine & Clutch Section

ENGINE, REPLACE

1200, 1300 & 1967-68 1500

1. Disconnect battery ground strap.
2. On early models turn off fuel tap. On later models pull fuel hose off and clip it.
3. Remove carburetor air cleaner.
4. Remove engine rear cover plate.
5. Disconnect wires from generator, ignition coil and oil pressure switch.
6. Disconnect accelerator cable from carburetor.
7. Loosen and turn distributor to allow vacuum unit to clear rear cover plate when engine is being removed.
8. Raise vehicle at least three feet off the floor.
9. Disconnect both heater control cables and loosen flexible heater pipes from engine.
10. Disconnect fuel hose from engine.
11. Remove nuts from both engine lower mounting bolts.
12. Pull accelerator cable from guide tube.
13. Place a roller jack under engine.
14. While holding the two upper engine mounting bolts, have an assistant remove the nuts.
15. Raise jack to support engine.
16. Withdraw engine far enough to allow clutch release plate to clear main drive shaft. Then lower jack and tilt rear of engine downward until it can be completely removed.

1965-66 1500 & All 1600

1. Disconnect battery ground strap.
2. Remove air cleaner.
3. Remove cables from generator, coil, oil pressure switch and automatic choke.
4. Detach accelerator cable at connecting link.
5. Remove oil dipstick and take off rubber boot between oil filler and body.
6. Loosen clip on bellows at cooling air intake housing and pull off bellows.
7. Remove rear engine support.
8. Raise and support vehicle on stands.
9. Disconnect flexible pipes between engine and warm air mixing boxes.
10. Disconnect heater flap cables.
11. Take warm air hose from carburetor pre-heater off engine.
12. Pull off fuel hose at front engine cover plate and seal it with a suitable plug.
13. Remove two lower engine mounting nuts.
14. Support engine with roller jack.
15. Hold two upper engine mounting bolts while an assistant removes nuts.
16. Pull engine back slightly until release plate clears main drive shaft.
17. Lower engine, being sure that clutch release plate or main drive shaft are not damaged.

Installation, All Models

When installing the engine, use care to prevent damage to the flywheel gland nut needle bearing and clutch release bearing. To facilitate entering the main drive shaft into the clutch plate and gland nut needle bearing, engage a transmission gear train to keep the mainshaft from turning and rotate the engine by means of the fan belt as required.

When installing the engine, first install the mounting bolts into the transmission case flange. Then press the engine against the flange, being sure it seats properly around the flange before installing the nuts. Tighten the upper nuts finger tight first, then the lower nuts. The final tightening should be done in the same order.

ENGINE, DISASSEMBLE

The following sequence of operations is recommended when disassembling the engine. Reverse the order of procedure to reassemble, and refer to the text which follows for details on the installation of the various components.

1200, 1300 & 1967-68 1500

1. Drain engine oil.
2. Remove hoses between fan housing and heat exchangers.
3. Remove front engine cover plate.
4. Remove rear engine cover plate.
5. Remove muffler.
6. Remove fan belt.
7. Pull off coil-to-distributor cable.
8. Remove fan housing with generator.
9. Remove intake manifold with preheating pipe.
10. Remove both heat exchangers.
11. Disassemble and remove cylinder deflector plates.
12. Remove crankshaft pulley.
13. Remove cylinder head cover.
14. Remove rocker shafts.
15. Remove push rods.
16. Remove cylinder heads.
17. Remove push rod tubes.
18. Remove deflector plates below cylinders.
19. Remove cylinders.
20. Remove pistons.
21. Remove oil cooler.
22. Remove oil pump.
23. Remove oil strainer.
24. Remove fuel pump.
25. Remove distributor and drive pinion.
26. Remove clutch and flywheel.
27. Disassemble crankcase.
28. Remove camshaft and crankshaft.

1965-66 1500 & All 1600

1. Drain engine oil.
2. Remove front engine cover plate.
3. Remove muffler.
4. Remove intake manifold and carburetors.
5. Disconnect heat exchangers.
6. Remove generator and belt.
7. Remove cooling air intake housing.
8. Remove crankshaft pulley.
9. Remove rear half of fan housing.
10. Remove fan.
11. Remove front half of fan housing.
12. Remove distributor and fuel pump.
13. Remove distributor drive pinion.
14. Remove oil cooler.
15. Remove rocker shafts.
16. Remove cylinder heads.
17. Remove cylinders and pistons.
18. Remove clutch and flywheel.

Fig. 1 Showing cylinder retainer in place when removing cylinder head

Fig. 2 Showing location of sealing ring (deep black) between cylinder shoulder and cylinder head. Series 1200, 1300 and 1967-68 1500

Fig. 3 Oil seals at ends of push rod tubes. All engines

19. Remove oil pump and strainer.
20. Disassemble crankcase.
21. Remove camshaft and crankshaft with connecting rods.

CYLINDER HEAD

Each pair of cylinders has one detachable cylinder head. The cylinder head is provided with cooling fins and incorporates shrunk-in valve seat inserts and valve guides. No gasket is used between the joining faces of the cylinder and cylinder head. Gaskets are used, however, between the flanges of the cylinder and cylinder head to prevent leakage of combustion gases.

NOTE: If it is intended to remove cylinder heads only, a suitable cylinder retainer can be made locally to prevent the cylinders from being withdrawn unintentionally and eliminates the danger of dirt entering the crankcase. Fig. 1 shows the retainer bolted to crankcase and positioned between cooling fins.

When installing heads the following points should be observed:

1. Check heads for cracks in combustion chamber and exhaust ports. Cracked heads must be replaced.
2. Check threads for spark plugs. If necessary, install Heli-Coil threaded inserts.
3. There is no gasket between upper edge of cylinder and cylinder head.
4. On 1200, 1300 and 1967-69 1500, fit new sealing ring between cylinder shoulder and cylinder head, Fig. 2.
5. On all engines, when installing cylinder head, make sure that oil seals at ends of push rod tubes are properly seated, Fig. 3.
6. Push rod tubes can best be centered by using a centering tool of the type shown (made locally) when installing cylinder head, Fig. 4.
7. Turn the tubes so that the seam is facing upwards. To ensure perfect sealing, used tubes must be stretched to the correct length before they are installed, Fig. 5. This operation must be carried out carefully to avoid cracking tubes.
8. Coat attaching nuts with graphite paste and screw them down until resistance can be felt. Then make an initial tightening with a torque wrench to 7 ft-lbs in the sequence shown in Fig. 6. The final tightening should be made in the sequence shown in Fig. 7 to the specified torque (see table).

VALVE MECHANISM

The camshaft is carried in three bearings machined in the crankcase. It is driven by the crankshaft by helical gears. The valves are operated by the cams via cam followers, push rods and rocker arms. Each cam operates in turn one of the valves of two opposed cylinders. The exhaust valves are plated with chrome-nickel steel.

Valves, Adjust

Valve lash should be adjusted only when the engine is cold and at approximate room temperature. To adjust the valves, crank the engine to the left of the fan pulley until both valves of the cylinder being adjusted are fully closed and the timing mark on the pulley is in line with the vertical joint faces of the crankcase.

1. Remove cylinder head cover.

Fig. 4 Centering push rod tubes with tool shown

Fig. 5 When installed, push rod tubes should be stretched, if necessary, to the following lengths (dimension "A"):

1200	1963-65	7.105-7.144"
1300	1966	7.480-7.520"
1500, 1600	1965-69	7.480-7.520"

Fig. 6 Initial tightening sequence of cylinder head

Fig. 7 Final tightening sequence of cylinder head

Fig. 8 Rocker arm mechanism

2. Set engine in firing position for No. 1 cylinder.
3. Check valve clearance with a feeler gauge. If adjustment is required, loosen the rocker arm adjusting screw lock nut and turn the adjusting screw until the specified clearance is obtained (see chart) and tighten lock nut.
4. Check and adjust remaining valves in the same manner.

Rocker Arm Mechanism, Fig. 8

1. Take off cylinder head cover, rocker shaft retaining nuts and lift off assembly with stud seals.
2. To install, first slip on the stud seals. Then install the mechanism in the reverse order of removal.
3. Make sure ball end of push rods rest centrally in rocker arm sockets.
4. To make valves rotate during operation, the rocker arm adjusting screws should contact valve stems slightly to the right.
5. Adjust valve lash. Install head cover, using a new gasket cemented to the cover all around. If gasket shows evidence of shrinkage as a result of prolonged storage, place it in lukewarm water before cementing it in place.

Push Rods & Tubes

When installing push rods and their tubes, be sure the tube seams are facing upward. If the old tubes are to be re-used, and to insure perfect sealing between tube and crankcase and/or cylinder head, they should be stretched to the dimension indicated in Fig. 5.

Valves, Remove

1. Using a suitable valve spring compressor, Fig. 9, press down on valve spring and remove valve locks and spring caps.
2. Lift off valve springs and take out valves. If the valve lock grooves are burred, remove the burr with a smooth file before attempting to remove the valve from its guide.
3. Place valves in a board with numbered holes to identify their location so that if re-used they can be returned to the original guide holes.

VALVE STEM CAPS: Valves with worn stem ends can be made usable by fitting caps (available from VW) on the stems, Fig. 10. The caps are merely placed on the stems before the rocker arms are fitted and do not need securing.

Valve Springs

Check the tension of all springs on a spring testing tool. If such a tool is not available, check the free length of each spring. Any spring that does not conform to the pressure specifications (see chart) within 10 per cent should be replaced. Likewise, any spring that stands shorter than the specified free length, or is distorted or cocked should be discarded.

Valve Guides

Inasmuch as the valve guides are shrunk (chilled) into position, it is not possible to remove them by pressing them out of the cylinder head in the conventional manner as damage to the cylinder head would most likely result.

Use a reamer or broach to remove carbon deposits from the guides. Then check the clearance between valve stem and guide, using a suitable plug gauge or a thin feeler gauge strip. If the clearance approaches the wear limit of .0063", replace the cylinder head with a new or factory-reconditioned one.

Camshaft & Timing Gears

1200, 1300 & 1967-68 1500 Engine: The camshaft is mounted in the crankcase in three split steel bearings with lead-coated working surfaces. Camshaft end thrust is on the No. 3 bearing which has a shoulder to take the thrust.

When installing these bearings, break the edges of the camshaft bearing bores slightly at the crankcase joint to prevent seizure due to pressure on the bearing shells. Fit the bearings so that the tongues engage in the recesses in the crankcase. Coat all bearings with oil before installing camshaft.

1. To remove, open the crankcase and take out the camshaft and gear assembly.
2. Examine riveted joint between gear and camshaft. Check camshaft bearing points and cam faces for wear. Cam faces must not be scored but must be smooth and square.
3. Check cam journals, cams and gear for damage. Slight damage may be corrected with a silicone-carbide oilstone; do not use a grinder.
4. Carefully clean camshaft of any abrasive material.
5. When installing the camshaft, be sure that the timing gear tooth marked "O" is placed between the two punch-marked teeth on the crankshaft gear, Fig. 11.

Fig. 9 Cylinder head mounted in valve remover tool (VW-311A)

Fig. 10 Cap used on worn valve stems

Fig. 11 Timing gear marks located for correct valve timing

SERVICE NOTE: To insure that the timing gears operate quietly, a backlash of .002" must be present. This check is made by rocking the gears back and forth with both hands while gradually turing the camshaft gear until it has made one complete turn. To obtain the specified backlash, camshafts are available with timing gears of various sizes, the standard size gear being marked with

Fig. 12 Heating piston with an electric piston heating tool (VW-205A) to expand it so that tight piston pin can be removed

an "O" etched on the inner face of the gear. Other gears are marked —1, +1, +2. The crankshaft gear is available in one size only.

CYLINDERS & PISTONS

The four cylinders are interchangeable and can be replaced separately together with the corresponding piston. The cylinders are provided with fins for efficient cooling.

The pistons are of light metal alloy fitted with three rings, the bottom ring being an oil control ring. Piston pins are full floating and are retained in place by lock rings.

PISTON MARKINGS: The symbols present on piston heads, Fig. 13, denote the following:

A. Arrow (indented or stamped on) must point towards flywheel when piston is installed.
B. Details of piston pin bore size indented or stamped on (S for black, W for white).
C. Paint spot indicating matching size (blue, pink, green).
D. The letter near arrow corresponds to the index of the part number of the piston. It serves as an identification mark.
E. Details of weight grading (+ or —) indented or stamped on.
F. Paint spot indicating weight grading (brown — weight, grey + weight).
G. Details of piston size in mm.

Cylinder Inspection

Volkswagen recommends that an inspection of cylinders be carried out by means of a dial gauge for inside diameters and gauge rings corresponding to the cylinder sizes. Cylinders should be measured about ½" below the upper edge.

When measuring the piston in its cylinder, if it is found that the clearance approaches the wear limit of .008", replace the piston and cylinder with another pair of the same size and weight. The piston must not be fitted separately if the corresponding cylinder shows signs of wear. If the cylinder of a damaged piston does not show signs of wear, it is usually sufficient to install a new piston of the same size and weight.

Pistons & Pins

1. Remove pistons from cylinders and mark them so that, if re-used, they can be installed in the original cylinders.
2. Remove piston pin lock ring and push pin out of piston. If pin cannot be pushed out it will be necessary to heat the piston with an electric piston heating tool, Fig. 12 to expand the piston. The pin may then be pushed out.
3. In all cases where the piston pin is not a light finger push fit in the cold piston, the piston should be heated. The pin should also be heated in order to avoid the rapid cooling of the piston bosses. As the steel pin has less expansion qualities than the aluminum piston when it is heated, the pin can easily be pushed into the piston.

Installation Of Cylinders

1. Before installing cylinders, check the seating surface of the crankcase, cylinder shoulder and gasket; all must be thoroughly clean as distortion of the cylinder may occur if dirt is present.
2. Be sure to use a new gasket between cylinder and crankcase.
3. Apply engine oil to piston and piston pin. Use a suitable compressor to compress piston rings, being sure to stagger the ring end gaps around the piston. The oil ring gap must always be at the top when pistons are in horizontal position in the engine.
4. Oil cylinder walls and slide cylinder over piston. Be sure crankcase studs do not contact cylinder cooling fins.
5. Install deflector plates. To prevent them from rattling, bend the plates as necessary until they bear tightly on the cylinder head studs.

Fig. 14 Checking crankshaft with engine installed. Use bracket (VW-659) and dial gauge

Fig. 13 Piston markings

6. When installing push rods and their tubes, be sure the tube seams are facing upward. If the old tubes are to be re-used, and to insure perfect sealing between tube and crankcase and/or cylinder head, they should be stretched to the dimension indicated in Fig. 5.

CRANKSHAFT

The crankshaft is fitted with four main bearings, No. 2 bearing (seen from the clutch) is the split type. No. 1 bearing is lead-coated and controls the crankshaft end thrust. The flywheel is held by a gland nut and in addition is secured to the crankshaft by four dowel pins. The crankshaft timing gear and distributor drive gear are held in place by woodruff keys. The fan pulley is bolted to the crankshaft. An oil seal is fitted to the clutch side of the crankshaft and an oil thrower and oil return thread to the pulley side.

Crankshaft, Replace

1. Open crankcase as outlined under *Crankcase* and remove crankshaft and camshaft.
2. Crankshaft bore in crankcase must have no sharp edges at the joining faces. Slightly chamfer edges, if necessary.
3. Check dowel pins for tightness.
4. Oil passages in crankshaft must have no sharp edges. Should foreign matter be embedded in main bearings, remove it with a scraper, using care not to remove any metal from the bearing shell itself.
5. Place one-half of No. 2 main bearing in crankcase.
6. Slide on No. 1 main bearing so that the dowel pin hole is toward flywheel.
7. Install crankshaft, making sure dowel pins are correctly seated in main bearings.
8. Note marks on timing gears when installing camshaft, Fig. 11.

Crankshaft, Overhaul

DISASSEMBLE

1. With crankshaft in a holding fixture,

Fig. 15 Checking crankshaft end play when engine is removed

remove woodruff key, oil thrower and No. 4 main bearing.
2. Remove retaining ring and take off distributor drive gear, spacer and crankshaft timing gear.
3. Remove No. 3 main bearing.
4. Remove connecting rods.

REASSEMBLE

1. First place Nos. 1, 3 and 4 main bearings in left crankcase half, noting proper position of dowel holes and oil holes which must register with oil passages in crankcase. Dowel hole in No. 1 main bearing must be towards flywheel. *NOTE: To facilitate fitting of main bearings on dowels when installing crankshaft, mark bearings at crankcase joining faces with a pencil.*
2. If dowel holes in crankshaft are worn, remove crankshaft and drill new holes 45 degrees away from the old holes and ream them to .315″.
3. Slide No. 3 main bearing in position and insert woodruff key for crankshaft gear and distributor drive gear.
4. Heat crankshaft gear in an oil bath and press into position. Slide spacer on crankshaft.
5. Heat distributor drive gear and press it in position.
6. Install retaining ring, using a suitable tapered guide to avoid damage to crankshaft journal. Check gears for proper seating after they have cooled.
7. Clean out oil passages and blow out with compressed air.
8. Slide No. 4 main bearing on crankshaft. Install oil thrower with its concave surface facing crankshaft pulley.
9. Insert woodruff key.
10. Install connecting rods.

Fig. 16 Measuring distance from crankshaft face to outer race of No. 1 main bearing with dial gauge (VW-292)

Checking Crankshaft End Play

Crankshaft end play should not exceed .006″. End play can be checked with the engine installed or removed.

With the engine installed in the vehicle, mount a dial gauge and bracket, Fig. 14, so the stem of the gauge contacts the crankshaft pulley. Mount the bracket on the rearmost crankcase stud. An end play reading is obtained by rocking the crankshaft back and forth at the pulley hub.

To check the end play with the engine removed, the dial gauge is mounted at the flywheel by one of the engine mounting bolts, Fig. 15.

Adjusting Crankshaft End Play

1. Force the installed crankshaft against the flywheel side of the engine (flywheel removed) to take up the play.
2. Insert dial gauge in flywheel seat, Fig. 16, and measure distance from crankshaft face to outer face of No. 1 main bearing.
3. Next place dial gauge on flywheel joint flange, Fig. 17, and measure depth of crankshaft seat.
4. The thickness of shims to be used is determined by the difference in both readings (including the paper gasket). The thickness of the paper gasket is .0078″ and is compressed by .0019″ in assembling. This leaves .0059″ to be considered when determining thickness of shimming. Three shims of the required thickness are to be installed. Never use more than one paper gasket.

Crankshaft Oil Seal

Oil losses at the flywheel side resulting from a leaky oil seal are frequently mistaken for a leak at the crankcase joining faces. Therefore, it is advisable always to check the crankshaft oil seal first whenever oil losses are noticed at the flywheel side. Replace the seal as follows:

1. Remove flywheel and oil seal.
2. Clean oil seal recess in crankcase and coat it with a thin film of sealing compound. If necessary, slightly chamfer the outer edge with a scraper, and clean recess of metal chips.
3. Install new oil seal, being sure it seats squarely on the bottom of the recess.
4. Install flywheel. Lubricate seal lip contact surface with oil.

CONNECTING RODS

The crankshaft ends of the four con-

Fig. 17 Measuring depth of crankshaft seat

necting rods contain replaceable bearings. The piston pin ends are provided with bronze bushings.

1. Remove crankshaft and place in a holding fixture. Unfasten and remove connecting rods.
2. Inspect piston pin bushing. The correct fit of a new bushing is indicated by a light finger push fit of the pin at room temperature.
3. Check connecting rod alignment.
4. Insert bearing shells in rods and install rods on crankshaft. Be sure identification numbers stamped on rods and caps are both on the same side.
5. After tightening rod bolts to the specified torque (see chart), and with bearings well lubricated with engine oil prior to assembly, rods must slide on the crankpin by their own weight. Stake or peen the bolt heads to prevent them from working loose.

CRANKCASE

The crankcase is a light-metal die casting in two parts. The crankcase halves are machined in pairs to very close limits; therefore, replacements must be made in pairs.

Fig. 18 Installation of distributor drive gear components

Fig. 19 Use a screwdriver to guide washer into place so it will not fall into timing gear chamber

DISASSEMBLE

1. Remove oil pressure switch.
2. Remove crankcase nuts. Keep cam followers of right crankcase half in position with suitable retaining springs.
3. Take off right-hand crankcase half, using a rubber hammer to loosen it. To avoid damage do not use metal tools to separate crankcase halves.
4. Remove crankshaft oil seal and camshaft end plug.
5. Remove camshaft, crankshaft, cam followers and bearing shells.

REASSEMBLE

1. Reverse disassembly procedure to reassemble, noting the following:
2. Examine crankcase for damage or cracks, and check studs for secure seating and oil leaks.
3. Remove all traces of sealing compound from crankcase joining faces. The joining faces must be perfectly clean and free of burrs. The edges of the main bearings should be slightly chamfered to obtain accurate matching of the crankcase halves. Oil passages should be flushed out and cleaned with compressed air.
4. Check oil suction pipe for secure seating and leaks.
5. Install cam followers.
6. Install oil pressure switch.
7. Note position of timing marks on timing gears and make sure crankshaft oil thrower is correctly installed.
8. Oil crankshaft bearing joints and install crankshaft and bearings.
9. Install camshaft, and camshaft end plug, using sealing compound on plug.
10. Install thrust washers and crankshaft oil seal, being sure seal rests squarely on bottom of its recess in crankcase.
11. Evenly spread a thin film of sealing compound on the crankcase joining faces. Be sure that no sealing compound enters oil return passages of crankshaft and camshaft bearings.
12. Keep cam followers of right crankcase half in position with retaining springs.
13. Join the crankcase halves and evenly tighten nuts with a torque wrench. First tighten the 8MM nut beside the stud of No. 1 main bearing; then tighten the 12MM nuts to specifications (see chart).

DISTRIBUTOR DRIVE PINION

REMOVAL

1. Loosen distributor clamp bolt and lift out distributor.
2. Remove distance spring on drive pinion, Fig. 18. Pull drive pinion out by twisting it counter-clockwise.
3. Remove washer under pinion, being careful not to drop it into the crankcase. **Note:** If the engine is in the car the washer can be removed with a magnet. If engine is out of the car, turn engine upside down so that washer can fall out.

INSTALLATION

1. Check fuel pump push rod drive surface on drive pinion and pinion teeth for wear. If badly worn, the gear on the crankshaft must be examined.
2. If washer under pinion is worn, replace with a new one, being careful not to drop it into the crankcase, Fig. 19.
3. Set No. 1 cylinder to the firing point and insert the distributor drive pinion. The offset slot in the top of the pinion must be toward the pulley, Fig. 20.
4. Insert distance spring, install distributor, time ignition and install fuel pump. **Note:** On late model cars the thrust surface of the distributor drive shaft in the left crankcase half is machined .196″ deeper. Also the distributor drive shaft is modified in that it has a thrust shoulder with a flat machined on one side, Fig. 21, in place of the reduced diameter toothing on the oil pinion. The thrust washer is still used.

CAUTION: This modified distributor drive shaft can only be removed and installed when No. 1 cylinder is at the firing point as the flat on the thrust shoulder is then toward the distributor drive gear. In this position the offset slot in the upper part of the shaft is at right angles to the crankcase joint. Any attempt to remove or install the shaft in another position will damage the distributor drive gear. This modified distributor shaft cannot be installed in the earlier crankcase.

Fig. 21 Modified drive shaft shown at right

Fig. 20 Narrow offset side of slot must face crankshaft pulley

ENGINE OILING SYSTEM

The oil pump, Fig. 22, is located on the gear side of the camshaft, from which it is driven. Oil is drawn from the bottom of the crankcase and forced into the oil passages by way of the oil cooler, Fig. 21. Some of the oil is fed via the main bearings through the drilled passages in the crankshaft to the connecting rod bearings. Oil is also fed to the camshaft bearings, and through the hollow push rods to the rocker arms. Cylinder walls, pistons and piston pins are splash-lubricated. The oil returns to the bottom of the crankcase where it is filtered by a gauze strainer at the lowest point before re-entering the circulation.

The oil cooler on the crankcase is positioned in the ducted air flow. This enables the oil to maintain its lubricating qualities even at high outside temperatures and at sustained high engine speeds.

Oil Strainer

1. The oil strainer is removed as indicated in Fig. 22.
2. When installing, check the suction pipe for tight and proper seating.
3. Clean strainer and remove traces of old gasket material.
4. Use new gaskets. Install strainer, making sure that suction pipe is correctly seated in strainer. If necessary, bend strainer as required.
5. Remove traces of old gasket from bottom plate. Straighten bent or distorted bottom plates to insure a proper seal.
6. Do not over-tighten nuts, especially when using thicker gaskets, to avoid bending bottom plates.

Fig. 22 Disassembled view of oil pump, cooler, strainer and filler (typical)

Note: The strainer can be provided with a magnet ring which will trap all metal abrasives contained in the oil circulation. The ring is held in the strainer by a spring. When cleaning the strainer, the magnetic ring should be removed.

Oil Pressure Relief Valve

Check the oil pressure relief valve when defects in the oiling system takes place. If the plunger sticks at top dead center when the oil is thick the oil cooler may be leaking. If the plunger sticks at bottom dead center the oil will flow directly back to the crankcase.

Oil Cooler

When removing the oil cooler with the engine in the vehicle or from an assembled engine out of the car, the fan housing should be removed first. If the oil cooler is leaking, check the oil pressure relief valve.

When installed, be sure the studs and cooler bracket are tight. The hollow ribs of the cooler should not touch one another and the partition sheet should not be loose. Use new gaskets.

Oil Pump

1. With the engine installed, the oil pump can be removed after the engine cover plate, crankshaft pulley and the cover plate below the pulley have been removed.
2. Remove pump cover and gears, Fig. 22.
3. Remove pump body with a puller.
4. Examine gears for wear. Backlash between gears should be .0012-.0031". End play without pressure of cover should be .0026"-.0072", with wear limit being .0079".
5. If idler gear pin cannot be tightened, install a new pump body.

Schematic diagram of engine oil flow

INSTALLATION

1. Install pump body with gasket.
2. Install pump drive shaft and turn it as required to allow tang on shaft to enter slot in camshaft. Then install driven gear.
3. Place a straightedge across pump body and use a feeler gauge between gears and straightedge to check clearance. With gasket removed, this clearance should not exceed .004". If cover is worn from contact with gears, plane it off or replace cover.
4. Use new accredited gaskets without sealing compound and replace cover. When tightening the nuts, make sure the position of the pump body is not disturbed.

COOLING SYSTEM 1200, 1300 & 1967-68 1500

Fig. 24 is a layout of the components of the cooling system. The engine is cooled by the fan which is attached to the generator shaft. The fan is driven by the crankshaft by an adjustable belt. The fan sucks in air through an opening in the fan housing, and the air cools the engine by being forced through the fins of the cylinders and cylinder heads.

Air flow is directed by the air deflector plates, some of which are located in the fan housing, the others cover the cylinders. The throttle ring at the air intake opening of the fan housing is thermostatically controlled to ensure that the operating temperature is quickly attained and steadily maintained.

Engine Cover Plates

1. If the deflector plates below the cylinders cannot be seated properly, bend them as required so they bear against the cylinder head studs to prevent them from working loose and causing a rattle.
2. When replacing the cylinder head cover plates, be sure the spark plug rubber caps are in good condition and seat properly. The cylinder cover plates must fit snugly on the fan housing to prevent loss of cooling air.
3. Before installing the engine front cover plate, check the condition of the weatherstrip and replace if necessary.
4. After the engine has been installed, the rear cover plate weatherstrip lips must straddle the plate. Be sure the washers are installed under the slotted screw heads, and see that the breather pipe grommet bears squarely on the cover plate.

Fan Housing

1. When installing the fan housing, be sure the air deflector plates are not

Fig. 23 Exterior view of 1200, 1300 and 1967-68 1500 engines

Fig. 25 Fan details. Dimension "A" is 0.70". Series 1200, 1300 & 1967-68 1500

loose and that the fan housing is not damaged in any way.

2. No air must be allowed to blow between the fan housing and cylinder cover plates. Bend plates into correct position, if necessary.
3. When inserting the throttle ring, screw it to the operating shaft holding plate, making certain that the throttle ring is not off center from the intake flange. Connect the return spring and adjust the throttle ring. Install ignition cable rubber holders in fan housing.

Fan, Replace

REMOVAL

1. Remove screws from fan cover.
2. Take off generator and fan.
3. While holding fan, and assistant may remove special nut.
4. Remove fan, spacer washers and nut.

INSTALLATION

1. With woodruff key seated in shaft keyway, place hub on generator shaft.
2. Insert washers and install fan.
3. Install and torque special nut to 40-47 ft-lbs.
4. Clearance between fan and cover should be 0.70", Fig. 25. To establish this clearance, insert spacer washers as required between carrier plate and hub. If only one washer is used, the other two should be placed between fan and lock washer.
5. Install generator in fan housing and secure with four screws.

Air Intake Control

1. The automatic air intake control should be inspected each spring and fall and adjusted if necessary.
2. If the throttle ring remains open or opens too early, the engine will attain its normal operating temperature too slowly. In some cases excessive fuel consumption and continuous "popping" through the carburetor will result due to prolonged cold operation.
3. If the throttle ring opens too much it may cause fan noise. If it opens too slowly during warm weather the

Fig. 24 Disassembled view of cooling system components. Series 1200, 1300 & 1967-68 1500

Fig. 26 Distance "A" from outer intake flange to edge of throttle ring is 0.98" to 1.18". Series 1200, 1300 1967-68 1500

Fig. 28 Insert crankshaft pulley so pin engages hole in fan. 1965-66 1500 & All 1600

Fig. 30 Belt tension is corrected by varying number of washers between pulley halves. Taking washers out increases tension and vice versa

engine will overheat during sustained high load conditions.

4. If the throttle ring remains open while the engine is cold, it may be due to a defective thermostat. To prevent the engine from overheating, the throttle ring opens automatically should the cooling system become inoperative.

ADJUSTMENT

1. When making the adjustment with the engine installed in the vehicle, first unhook the return spring.
2. Release throttle ring operating lever.
3. Operate engine until upper end of thermostat contacts the support upper stop.
4. Adjust throttle ring to open 0.98" to 1.18", Fig. 26.
5. Tighten operating lever, connect return spring and make sure throttle ring and linkage moves freely in all positions.

Fan Belt, Adjust

1. Proper fan belt tension is attained when a deflection of about ⅝" is present when the belt is pressed firmly with the thumb midway between the pulleys.
2. To adjust, insert a screwdriver in the slot cut into the inner half of the generator pulley and support it against the generator housing upper bolt. Then remove pulley outer half.
3. Install spacer washers between the two pulley halves as required to obtain the correct belt tension. Belt slackness is taken up by removing washers. If belt is too tight, add washers as required.

COOLING SYSTEM 1965-66 1500 & ALL 1600

NOTE: The engine must always be removed when performing operations on the fan or crankshaft pulley.

Crankshaft Pulley, Replace

1. Remove muffler and generator.
2. Remove cooling air intake housing.
3. Remove plastic cap on pulley.
4. Remove pulley bolt and pulley.
5. Reverse procedure to install, observing the following points:
6. Use a proper gasket between pulley and fan. Insert pulley so that pin engages hole in fan, Fig. 28. Torque pulley to 94-108 ft-lbs.

Fan, Replace

1. Remove crankshaft pulley, coil, rear fan housing half, and use a suitable puller to remove fan.
2. During installation, check condition of oil return thread on fan hub. Press fan on crankshaft, attach rear fan housing half, install coil and pulley.

Fan Housing, Replace

1. Remove crankshaft pulley, rear fan housing half and fan.
2. Unhook linkage and spring at right-hand air control flap.
3. Remove attaching screws and front fan housing half.
4. Before installing, check front fan housing half for distortion and damage.
5. Slide a suitable centering tool on

Fig. 27 Exterior view of 1965-66 & All 1600 engines

Fig. 29 Arrow indicates where front lug contacts left crankcase half. 1965-66 1500 & All 1600

Fig. 31 Automatic cooling control. 1965-66 1500 & All 1600

crankshaft and install front fan housing half, being sure it is sealed correctly in cylinder cover plates.

6. Insert mounting screws and tighten lightly. Turn fan housing halves to the left until lug contacts left crankcase half, Fig. 29.
7. Tighten two lower mounting screws securely.
8. Loosen nuts on breather support until it can be moved.
9. Insert and tighten upper fan housing half mounting screws. Then tighten breather support nuts fully.
10. Remove centering tool and connect linkage and spring to right-hand air control flap.
11. Install fan and rear fan housing half.

Check and Adjust Belt Tension

NOTE: Tension is correct if the belt yields about ½" when pressed firmly at its center with thumb. Belt should not show any signs of excessive wear such as frayed edges or cracks. Oily belts can often be made usable by washing in solvent and rinsing in clear water. Petroleum products must not be used for this purpose.

1. To adjust belt tension, remove air intake housing cover.
2. Hold generator pulley with a suitable wrench and remove nut.
3. Remove sleeve and outer pulley half.
4. Arrange spacer washers as required.

NOTE: Tension is corrected by varying the number of washers between pulley halves, Fig. 30. Taking washers out increases tension and vice versa. Install outer half of pulley. All washers not used between pulley halves must be placed between rear half and sleeve so that total number remains the same.

5. Install nut and housing cover.

Fig. 32 Checking preheating pipe valve for free movement. 1965-66 1500 & All 1600

Fig. 33 Preheating pipe valve assembly. 1965-66 1500 & All 1600

Fig. 34 Details of preheating pipe valve. 1965-66 1500 & All 1600

Cooling Air Control

1. Referring to Fig. 31, remove cylinder cover plates and warm air ducts.
2. Unhook return spring at support plate.
3. Detach throttle flap rod at relay lever.
4. Remove front half of fan housing.
5. Remove throttle flaps screws (6).
6. Remove clip at right-hand end of flap shaft and remove shaft out to the left.
7. Reverse procedure to install, being sure that rubber stop for right-hand flap is in position.

Adjustment

1. Assemble all parts of linkage and lubricate joints with graphite paste.
2. Press flaps into closed position. If flaps do not close evenly, loosen one flap and turn it on shaft.
3. Tighten clamp screw on relay lever.
4. Connect long end of spring to flap and short end to support plate. Spring must be between support plate and bent lug. When spring is connected there should be a gap of about ½" between lower edge of flap and fan housing.

NOTE: When necessary, the air control linkage can be adjusted with the engine in the vehicle if the right-hand cylinder cover plate is removed.

INTAKE & EXHAUST SYSTEMS

Intake Manifold

1965-66 1500; All 1600

1. To remove intake manifold and preheating pipe (single carburetor engine only), first remove air cleaner.
2. Disconnect accelerator cable.
3. Pull off cable at automatic choke.
4. Pull fuel and vacuum lines off carburetor.

Fig. 35 Warm air mixture thermostat adjustment. 1965-66 1500 & All 1600. Valve must contact housing at "A"; preload adjustment at "b" is 3/64"

5. Remove bolts and nuts at cylinder heads and exhaust pipes.
6. Remove intake manifold with preheating pipe.
7. Remove manifold gaskets in cylinder heads.
8. Before installing, see that manifold flanges are clean and smooth and not cracked.
9. Use new manifold gaskets.
10. Make sure when installing manifold that flange holes align correctly with studs and tapped holes. If necessary, straighten manifold. If it has been heated, see that no scale remains in the interior.
11. Check preheating pipe valve for free movement, Fig. 32.

Series 1200, 1963 to July 1964

1. Remove fan housing with generator.
2. Remove nuts and screws on cylinder heads and on exhaust flanges.
3. Take off intake manifold with preheating pipe.
4. Remove cylinder head sealing rings.
5. Before installing, see that intake manifold and preheating pipe flanges are flat and undamaged and check for cracks.
6. Use new gaskets in cylinder heads and at flanges.
7. When manifold is installed all flange holes must align properly with studs and threaded holes. To eliminate stress, pipes should be straightened. If pipe is heated see that all scale is removed from interior.
8. Tighten screws and nuts uniformly.

Preheating Pipe Valve Thermostat

1965-66 1500 & All 1600

The pre-load angle of the thermostat spring need only be checked if a new throttle valve has been installed. This is accomplished as follows:

1. Press bi-metal spring out of retaining lug on segment, Fig. 33.
2. Open throttle valve fully. Looped end of spring must then be located as shown.
3. If spring angle is not correct, loosen screw and move segment until spring loop and recess are correctly positioned.
4. Before tightening screw, be sure that the segment tabs are hard against edge of plate.

Installation

When installing the throttle, check angle of bi-metal spring as directed above. Install throttle so that bi-metal spring is outward, Fig. 34. Fit new gaskets for the preheater pipe.

NOTE: Every 3000 miles see that the throttle valve shaft moves easily. This is done by pulling the operating lever, Fig. 34, up with a suitable hook. If the throttle shaft is stiff in operation, hook the bi-metal spring out of the segment and remove the throttle. Lubricate the shaft bearings through the holes in the flange with one or two drops of oil. If this does not free the shaft properly, a new throttle valve should be installed. This also applies when the bi-metal spring is damaged.

Fig. 36 Sectional view of clutch. Some models use a diaphragm spring type clutch cover and a ball release bearing in place of the carbon thrust ring

Warm Air Mixer Thermostat

1965-66 1500; All 1600

1. When necessary to install a new thermostat, screw it on to the threaded pin about two turns. Install deflector plate.
2. Place fresh air feed valve in adapter and screw it on tightly.
3. Screw thermostat down until valve contacts mixer housing, Fig. 35.
4. Screw thermostat down a further 1 to 1½ turns to give a preload of approximately $\frac{3}{64}$".
5. Secure thermostat with lock nut.

CLUTCH

The single-plate clutch, Fig. 36, is attached to the flywheel. The driven plate is splined to the main drive shaft. The clutch operating shaft and clutch release bearing are located in the transmission case.

Clutch, Replace

REMOVAL

1. Remove engine.
2. Loosen clutch cover a turn or two at a time so that the spring pressure is released gradually and evenly so as not to distort the clutch cover.
3. With all bolts removed, lift off clutch cover and take out driven plate, Fig. 37.

INSTALLATION

1. Clean clutch contact surface of fly-

Fig. 37 Removing and installing clutch

Fig. 38 Clutch release bearing installed

wheel and inspect it for wear. If necessary, the flywheel may be reground to a limit of .008″ and polished with emery cloth. If damage is too severe for this operation, replace flywheel.

2. Check clutch release bearing for wear and replace the complete bearing if necessary. Note correct position of retaining springs.
3. Pack needle bearing in flywheel gland nut with universal grease.
4. Install driven plate, using a suitable pilot mandrel (VW-219) to be sure it is centered correctly.
5. Note proper position of clutch cover locating lugs in flywheel. Then gradually and evenly tighten clutch cover-to-flywheel bolts.

Release Bearing, Replace

1. Remove engine. Take off release bearing retaining springs and remove release bearing.
2. Inspect carbon thrust ring of release bearing for wear and cracks; if damaged, install a new bearing. The thrust ring should not be replaced separately as it will be damaged when it is pressed into position.
3. Note position of retaining springs, Fig. 38.
4. After engine is installed, adjust clutch pedal free play.

Pedal Free Play, Adjust

1. Release lock nut on threaded cable end, Fig. 39.
2. Adjust clutch clearance by turning the adjusting nut on the cable end to obtain a clutch pedal free play of 0.40″ to 0.80″.
3. Depress clutch pedal a few times and recheck the adjustment.

Fig. 39 Adjusting clutch cable end to establish pedal free play

Fuel & Electrical Section

CARBURETORS

SERIES 1200, 1300 & 1967-68 1500

Figs. 1, 2 and 2a illustrate sectional views of the three basic carburetors in use. Fig. 1 has a manually operated choke while Figs. 2 and 2a are provided with automatic chokes.

Idling Adjustment

1. Normal idle speed usually requires that the volume (mixture) control screw be backed out 1¼ to 1½ turns from its seated position. When making the adjustment of the automatic choke carburetor, be sure that the idle speed adjusting screw is not resting on one of the steps of the fast idle cam.
2. With engine running at normal operating temperature, turn the idle speed screw in or out to obtain a speed of 550 rpm.
3. Turn volume control screw clockwise until engine speed begins to slow down. Then turn the screw in about ¼ turn in the opposite direction. A final adjustment may require that the volume control screw be turned slightly in either direction to get the engine to idle smoothly.
4. The adjustment is correct if the engine continues to run when the throttle is opened and closed quickly or when the clutch pedal is depressed. If the engine stalls the idle mixture is too lean; turn the volume control screw out slightly (about ⅛ turn). If the engine stalls when the throttle is closed suddenly, as when applying the brakes, the idling mixture is probably too rich.
5. If the engine idle is rough after the adjustments have been completed, check for damaged intake manifold flange gasket, a cracked or loose intake manifold or an improperly adjusted fuel pump.

Fig. 1 Solex carburetor 28 PCI with manual choke

Carburetor Service

In servicing the carburetors, refer to

Fig. 2 Solex carburetor 28 and 30 PICT-1 with automatic choke

Figs. 3 through 8 and note the following:

1. Check needle valve for leaks. Examine needle valve gasket for damage and see that it is properly installed to prevent leaks.
2. On manual choke units, check choke valve spring and choke valve shaft clearance. Make sure that choke poppet valve opens easily and check for perfect sealing.
3. On automatic choke units, check heater element and bimetal spring; if either of the parts is damaged the complete ceramic plate must be replaced. *Note: When installing the ceramic plate with bimetal spring heater element, be sure that the marking on the ceramic plate corresponds with that on the spring housing.*
4. On manual choke units, when the air correction jet is installed, a clearance of .020" should be present between the shoulder of the jet and the spray well face to prevent the face from cracking.
5. On all units, see that the pump diaphragm is not leaking. A "flat spot" when the throttle is opened suddenly is an indication of a leaky diaphragm.
6. Check the float for leaks by dipping it in hot water. Air bubbles will appear if the float is punctured.
7. On manual choke units, install the venturi as indicated in Fig. 8.
8. On all units, be sure the throttle valve shaft is not loose. Excessive looseness causes excessive flow into the carburetor which affects starting and idling operation. If necessary, throttle shaft may be re-bushed to eliminate looseness.
9. Replace volume control screw if its tip is damaged. If the tip has broken off be sure to remove the broken piece from the casting, and see that the screw seat in the casting is not damaged.
10. On manual choke units, the word "oven" on the float toggle lever must face upward.

1965-66 1500; All 1600 Twin Carburetor System

The twin carburetor system has two car-

Fig. 2a Solex 30 PICT-2 carburetor disassembled. Used on 1968 1500

Fig. 3 Solex carburetor 28 PCI disassembled

Fig. 6 Carburetor lower body. Solex 28 and 30 PICT-1

Fig. 4 Automatic choke components. Solex 28 and 30 PICT-1

Fig. 5 Carburetor lower body. Solex 28 and 30 PICT-1

Fig. 8 Install venturi with curved end up. Solex 28 PCI

buretors of the type shown in Fig. 9. The carburetors are attached to the cylinder heads with short intake pipes that are connected by a balance pipe. The carburetors are left and right handed and cannot be interchanged; they are operated by rods and ball joints and relay levers.

The carburetors have automatic chokes, accelerator pumps and power fuel systems. The vacuum for the spark advance mechanism is taken from the left-hand carburetor only. Intake air passes through a common air cleaner, via distribution ducts to the carburetors.

Carburetor Service

When checking and assembling the carburetor, note the following points when checking the individual parts:

Upper Body

1. Check float needle valve for leakage and spring-loaded ball for ease of movement. It should not be possible to blow air through the valve when the needle is pressed lightly on the seat.
2. Check height of injector tube opening with a T-scale as shown, Fig. 10, from upper part of carburetor and adjust if necessary by bending carefully.
3. Check height of power tube fuel opening, Fig. 11, from upper part of carburetor and correct, if necessary, by bending carefully.
4. Check choke valve shaft and vacuum piston for ease of movement.
5. Check heater element and bi-metal coil. If either part is damaged the complete cover must be replaced.

IMPORTANT: The arrangement of the bi-metal coils in the automatic choke covers is different for right

Fig. 9 Solex 32 PDSIT carburetor, two are used on twin carburetor engines

Fig. 10 Checking height of injector tube opening (.590" for 1500 models and .470" for 1600 models)

Fig. 11 Checking height of power tube fuel opening (.413" for 1500 models and .590" for 1600 models)

and left carburetors, Fig. 12. The hook-shaped ends of the coils face to opposite sides. Covers are marked externally: "Li" for left unit; "Re" for the right-hand carburetor. When cover is installed the intermediate lever must engage the hook on the bi-metal coil.

6. Install and turn choke cover so that mark is in line with lug on upper part of carburetor and tighten screws, Fig. 13.

Lower Body

1. When tightening pump cover screws, press pump lever down so that diaphragm is in pressure stroke position. *Spitting in carburetor on sudden acceleration usually indicates a leaking pump diaphragm.*
2. Place float in hot water and check for leakage. If bubbles appear, float is leaking and must be replaced.
3. Check throttle valve shaft end play. *Excessive play encourages the entry of secondary air and is detrimental to starting and idling.*
4. Check idle mixture screw; the tapered part must not be grooved, damaged or bent.
5. Install venturi in carburetor body so that the cutaway is at the discharge arm.
6. The end of the power fuel pipe should be roughly in the center between discharge arm and venturi. Moreover, the choke valve must not contact pipe as it closes.
7. The accelerator pump injector pipe must be positioned so that the fuel is sprayed into the throttle valve gap when throttle is opened. *The pipe position should be corrected as necessary but must be moved sideways only; height must not be altered.*
8. Check length of pull rods with a measuring jig which can be made locally, Fig. 14. Both ball joint locknuts should be sealed with paint afterwards.
9. After installing operating rod for automatic choke stop lever, adjust as follows:
   a. Close choke.
   b. Screw idle adjusting screw out so that throttle valve is closed.
   c. Adjust both nuts on operating rod so that there is a gap of .021-.023" at throttle valve when choke valve is closed, on 1965-66 1500 and .024-.026" on all 1600, Fig. 15. Gap must be measured with a wire gauge.
   Throttle valve should be pressed in closed position lightly while measuring.
   d. Tighten nuts firmly and lock, being sure that pull rod and throttle valve lever move easily.

Idle Adjustments

1. Take off right-hand connecting rod.
2. Turn idle adjusting screw until

Fig. 12 Arrangement of automatic choke covers

Fig. 13 Adjust automatic choke by turning choke cover so that mark is in line with lug on carburetor

Fig. 14 Length of pull rods should be adjusted to approximately 3.89" at "A"

Carburetor, left side

Fig. 16 Solex PHN-1 carburetor used on 1965-66 1500 with one carburetor

throttle valve is completely closed. Then slowly screw it in until it just contacts throttle valve lever, and give it a further ½ turn inward.

3. Turn in idle mixture screw until its point comes to rest on its seat, then back it out 1½ turns.
4. Warm up engine to operating temperature.
5. Remove oil bath air cleaner.
6. Connect cables for automatic choke cover and coil.
7. Start engine and connect accelerator cable rod at the three-arm lever.
8. Set idle adjusting screws on both carburetors the same amount so that an idling speed of 700 to 750 rpm is obtained.
9. Slowly screw in idle mixture screws on both carburetors until engine begins to slow down. Turn screws out until engine runs smoothly and then turn them out a further ¼ turn.

SINGLE CARBURETOR SYSTEM

This carburetor, Fig. 16, is a side-draft Solex unit which is distinguished by the fact that the induction passage is horizontal and below the float chambers. With this design the discharge openings for idling and normal running mixtures are below the level of the fuel which accounts for the unusual internal construction of the carburetor. All the drillings for the individual systems pass up through the carburetor body to the cover and from there down to the various discharge ports in the choke tube.

The carburetor has an automatic choke, an accelerating pump, a power fuel system and a double vacuum drilling for the ignition advance mechanism.

Fig. 15 Adjust length of operating rod so throttle valve opening is .021" to .023" when choke valve is closed on 1500 and .024-.026" on 1600

Fig. 17 Adjusting accelerator pump

Fig. 18 Adjusting throttle valve gap

Fig. 19 Adjusting automatic choke (1st step)

Carburetor Service

When checking and assembling the carburetor, the following points should be observed:

Float Chamber Cover

1. Check float needle valve for leakage. It should not be possible to blow air through the valve when the needle is pressed lightly to its seat.
2. Examine condition of needle valve gasket and see that gasket seats properly on installation.
3. Check gasket between upper and lower parts of carburetor.

Carburetor Body

1. Check automatic choke bi-metal spring and heater element; if either of these parts is damaged, install a new choke cover.
2. Check operation of spring for fast idle cam lever. Lubricate steps on cam.
3. When installing choke cover, see that hooked end of bi-metal spring engages with operating lever. Turn choke cover so that mark on cover is aligned with lug on choke housing.
4. Dip float in hot water. If bubbles appear, float is leaking and must be replaced.
5. Check throttle shaft clearance. Excessive clearance encourages the entry of secondary air and has a detrimental effect on starting and idling conditions. If necessary, holes for throttle shaft must be bushed.
6. Examine tapered portion of idle mixture screw and replace if tip is bent or broken.
7. The large hole in accelerator pump cover must be toward carburetor flange.

Fig. 21 Electro-Magnetic pilot jet used to prevent engine from "running-on" when ignition is turned off

Accelerator Pump, Adjust

The accelerator pump on the carburetor is set so that when the choke is fully open and the throttle valve is in the idling position, there is a clearance of .024 to .040" between pump lever and plunger.

When trouble is experienced with flat spots which are caused by too small or too large injection quantities, the accelerator pump can be set with the adjusting screw, Fig. 17. Experience has shown that the engine requires a larger amount of fuel at low temperatures and a smaller amount at high temperatures.

If the injection quantity is too small, turn adjusting screw to the left; injection will then commence earlier. If the injection quantity is too large, turn adjusting screw to the right; injection will then commence later. Usually a half to a full turn is sufficient. The setting should always be checked by road testing afterwards.

Throttle Valve Gap, Adjust

When the automatic choke has closed the choke valve, the stop lever rests on the highest step of the fast idle cam. At this position the throttle valve should be opened to a definite angle. This angle corresponds to a throttle valve gap of .031 to .035" and can be measured with a wire feeler gauge, Fig. 18.

If the gap is smaller, the cold engine will start badly and stop again quickly. If the gap is too large, the idling speed will be too high and the engine will run too fast.

Automatic Choke, Adjust

1. Remove carburetor and choke cover.
2. Close choke valve. The stop screw (1), Fig. 19, in the stop lever should be on the highest step of the fast idle cam (2).
3. Turn stop screw until gap at throttle valve is .031 to .035", Fig. 20.
4. Seal stop screw with paint afterwards. *All carburetors are adjusted in this manner. In isolated cases, however, the screw works loose and this alters the opening angle of the throttle valve.*

Idling Adjustment

1. Set engine speed to approximately 550 rpm with idle adjusting screw.
2. Turn idle mixture screw in slowly until engine speed starts to drop. Then turn it to the left until engine runs smoothly. From this position, turn idle mixture screw out about ¼ turn.
3. Regulate engine speed as necessary. The adjustment is correct if the throttle can be opened and snapped closed quickly without stalling when engine is warm and clutch pedal is depressed.

Fig. 20 Adjusting automatic choke (2nd step)

EMISSION CONTROL SYSTEM

The control of exhaust emissions is accomplished by the use of special carburetor, distributor and a throttle positioner. The purpose of the throttle positioner is to open the throttle slightly when the vehicle is over-running the engine, thus preventing the intake manifold vacuum from rising as high as it would with a closed throttle. Even on deceleration, the engine receives an adequate charge of combustible mixture and stops the fuel passing into the exhaust unburned. This also prevents backfiring in the muffler.

Idling Adjustment

1. Be sure timing is set to TDC.
2. With engine warm, connect a tachometer and set idling speed by turning the idle screw, Fig. 23.
3. Turn volume control screw, Fig. 23, to right until speed starts to drop. From this position turn volume screw to left until engine runs fastest. If necessary, regulate engine speed again with the idle screw.

Throttle Positioner Adjustment

Before attempting this adjustment the engine should be thoroughly warmed up and the automatic choke fully open.

1. Connect a tachometer and turn the adjusting screw on the throttle positioner clockwise until the stop washer on the pull rod contacts the throttle positioner housing, Fig. 23a. Engine speed should then be between 1700 and 1800 rpm.
2. If speed is higher, lengthen the pull rod. If the speed is lower, shorten the pull rod. Then turn the adjust-

Fig. 22 Main jet with altitude corrector

Fig. 23 Adjusting idle speed on Solex 30 PICT-2 carburetor with exhaust control system

ing screw on the throttle positioner counterclockwise until the idle speed is 850 rpm.

3. Increase the engine speed to 3000 rpm and release the throttle lever. The time taken for the speed to drop from 3000 rpm to 1000 rpm must be between 3 and 4 seconds. If the time taken is shorter, turn the adjusting screw clockwise. If the time taken is longer, turn the adjusting screw counterclockwise.

ELECTRO-MAGNETIC PILOT JET

On 1500 single carburetor engines, this jet, Fig. 21, is fitted in production. The jet can be service installed on 1200, 1300 and twin carburetor engines on which "running-on" cannot be eliminated. The pilot jet is fitted with a cut-off valve that cuts off the supply of fuel as soon as the engine is switched off, thus effectively stopping engine from continuing to run when ignition is turned off.

The needle in the pilot jet is operated electro-magnetically and closes the pilot jet when the ignition is switched off so that fuel can no longer flow through the jet. When the ignition is switched on, the jet needle is withdrawn and the jet cleared.

Service

If "running-on" occurs on an engine that is already fitted with an electro-magnetic pilot jet, the cut-off valve should be checked as follows:

1. Pull cable off terminal.
2. Check if screw is in tight.
3. Switch ignition on and touch terminal with cable end. The needle should move in and out with a ticking noise as the cable makes and breaks contact. *With the cable end off, needle moves toward carburetor and closes jet. With cable end on, needle moves away from carburetor and opens jet.*
4. If the cut-off valve does not work when checked in this manner or if the engine still tends to "run-on", the cut-off valve should be replaced.

NOTE: If the valve fails in operation, the needle can be withdrawn by turning the screw, Fig. 21. Turning the screw as far as it will go to the right closes the needle valve; turning screw all the way to the left opens the needle valve. In the opened position the cut-off valve is switched off and the fuel flow to pilot jet is open continuously. The jet can be screwed off the cut-off valve and blown out.

Fig. 23a Adjusting throttle positioner

MAIN JET WITH ALTITUDE CORRECTOR

1965-66 1500 Single Carburetor Engines

In order to ensure satisfactory mixture formation in the carburetor at high altitudes, the main jet carrier can be replaced by an altitude corrector with a suitable main jet, Fig. 22. (The twin carburetor engine cannot be fitted with this device.)

At one end of the altitude corrector is the main jet through which fuel coming from the float chamber has to flow. At the end opposite to the main jet, the pressure unit is screwed into the housing of the corrector to locate it axially. The other end of the pressure unit carries the needle which moves freely in the passage leading to the main jet. When the pressure unit expands due to the change in atmospheric pressure at high altitudes, the needle throttles the fuel flow to the main jet to suit the changing conditions.

When the vehicle is operated at sea level, the needle in the corrector moves into a position where it has no influence on fuel consumption.

IMPORTANT: When the altitude corrector is assembled, the pressure unit is set with the regulating nut which is secured with a lockplate. This setting must not be altered under any circumstances.

FUEL PUMPS

NOTE: From August 1965 (Engine No. D/F 000 001) a valve that cuts off the flow of fuel when the engine is not running, is fitted in the top half of the fuel pump. On this pump the filter is at the side and can be removed for cleaning by taking out the screw plug. The valve formerly installed in the fuel line has been discontinued. The new pump is marked VW-7. Delivery capacity and pressure remains the same of other pumps.

Fig. 24 Solex fuel pump. 1963-65

Fig. 25 Bosch distributor with centrifugal and vacuum advance (early models)

Fig. 26 Bosch distributor with vacuum advance only (typical)

The fuel pump is actuated mechanically from an eccentric on the distributor drive shaft.

To remove, disconnect fuel lines from pump. Remove nuts from mounting studs at flange and take off pump. Remove push rod, intermediate flange and gasket.

ADJUSTING PUMP STROKE: On Fig. 24 pump the range is .31″ to .51″. On the pump the stroke is about .16″ (roughly $\frac{5}{32}$″). The stroke is measured from the fuel pump contact flange (including gaskets) to the projecting push rod end.

Rotate the engine to check the pump stroke. Adjust the stroke by installing the necessary number of gaskets to the intermediate flange. Do not install less gaskets than required as this would have a detrimental effect on the diaphragm and drive mechanism.

INSTALLATION, Fig. 24 CAUTION: Do not insert the push rod until the intermediate flange has been installed as there is danger that it may slip past the guide in the flange into the crankcase.

1. Fill lower pump chamber with universal grease.
2. Install fuel pump so that inspection cover faces toward the left. Re-tighten nuts after engine has been warmed up. Connect fuel line and hose.

DISTRIBUTOR

Breaker Points, Adjust

1. Remove distributor cap and rotor.
2. Crank engine until fiber block on breaker arm rests on highest point on cam lobe.
3. Loosen lock screw of fixed breaker point.
4. On the unit shown in Fig. 25, turn the eccentric adjusting screw until the correct gap of .016″ is obtained.
5. On the unit shown in Fig. 26, insert a screwdriver between the two small pins on the contact breaker plate and in the slot at the end of the fixed point. Turn the screwdriver until a clearance of .016″ is obtained.

Note: When the points have been adjusted, the ignition timing must be re-set as an alteration of .004″ in the point gap alters the ignition timing about 3 degrees.

Ignition Timing

IMPORTANT: When setting the timing on engines with fuel injection or exhaust control system a timing light must be used and the engine must be warmed.

Fig. 27 Ignition timing marks on crankshaft pulley. 1965-66 1500 & All 1600

The use of a timing light is also recommended on all other models as this method does provide a more accurate setting. However, the previous method of setting timing on a cold engine by using a test lamp the same voltage as the car may still be used on other than fuel injected or exhaust controlled engines as follows:

1965-66 1500; All 1600

1. Referring to Fig. 27, remove air intake housing cover.
2. Turn engine at the generator until the right-hand mark on the crankshaft pulley is aligned with the setting surface on the fan housing and the rotor arm points to the No. 1 cylinder mark on the edge of the distributor housing.

IMPORTANT: The ignition can only be set when No. 1 cylinder is at top dead center on the compression stroke. The firing point of No. 3 cylinder is then 4 crankshaft degrees later than that of No. 1 cylinder.

3. Loosen clamp screw on distributor retainer.
4. Rotate distributor body clockwise until the breaker points are closed and then slowly counterclockwise until the points just begin to open and the test lamp lights.
5. Tighten distributor retainer clamp screw, reinstall rotor and distributor cap.

1200, 1300 & 1967-68 1500

1. Crank engine until mark on crankshaft pulley (see *Tune Up* table) lines up with the vertical crankcase joining faces and the distributor rotor arm is in No. 1 firing position (see mark on rim of distributor base).
2. Loosen clamp screw of distributor.
3. Connect one lead of a 6-volt test lamp to No. 1 at distributor and the other to ground.
4. Switch on ignition.
5. Rotate distributor body clockwise until breaker points are closed and then slowly counter-clockwise until points are just about to open and the test lamp lights.
6. Tighten clamp screw on distributor.
7. Install distributor cap and rotor.

Distributor, Replace

1. On early distributors, Fig. 25, disconnect vacuum line from vacuum chamber, and lead from No. 1 terminal at distributor. On later units, Fig. 26, remove vacuum pipe at distributor and disconnect lead No. 1 at ignition coil.
2. Remove distributor cap.
3. On early units, remove clamp screw at distributor retainer. On later units, remove retaining bracket screw or nut on crankcase.
4. Lift out distributor.
5. Reverse the procedure to install the distributor, noting of the following:
6. On 1200, 1300 and 1967-68 1500, position No. 1 cylinder at firing point. The slot in the distributor drive pinion must be positioned as shown in Fig. 28, with small offset side of slot toward pulley and ignition mark on pulley aligned with joint in crankcase.

   On 1965-66 1500 and all 1600, refer to Fig. 30 and place No. 1 cylinder at firing point. The slot in the drive pinion must then be at an angle of 60° as shown and the small segment on the head of the drive shaft towards the coil.
7. When inserting the distributor, turn distributor shaft until the rotor points to the mark for No. 1 cylinder on the distributor housing and the distributor shaft engages in the drive shaft slot after being turned slightly back and forth. (See Fig. 29 for 1200, 1300 and 1967-68 1500.)
8. Adjust ignition timing.

Fig. 29 With ignition mark on pulley in line with crankcase joint, rotor points to No. 1 mark on distributor housing. Series 1200, 1300 & 1967-68 1500

Fig. 28 Note position of offset slot in distributor drive pinion. Series 1200, 1300 & 1967-68 1500

GENERATOR, REPLACE

Series 1200, 1300 & 1967-68 1500

1. Disconnect cables from regulator.
2. Remove carburetor and fan belt.
3. Disconnect generator mounting strap.
4. Remove throttle ring and screws on both sides of fan housing. Raise housing a few inches.
5. Remove four screws on fan cover and take off generator and fan.
6. When installing, make sure that fan housing seats properly against cylinder cover plates all around. Also note concentric position of throttle ring.

1965-66 1500 & All 1600

1. Remove cables from generator.
2. Remove air intake housing cover and remove drive belt.
3. Unfasten and remove generator.
4. The generator should be installed so that the mark on the housing (notch) is in line with the mark on the clamping strap.
5. The clearance between the belt and the air intake housing must be at least 11/64″ and the generator pulley properly aligned with the crankshaft pulley.

IMPORTANT: If the markings can no longer be seen or if another generator is installed, the openings in the generator housing and those in the cooling air housing must be aligned so that the generator is properly cooled, Fig. 31. The generator should be turned so that the D+ terminal is at the angle indicated in the illustration.

6. Be sure that the boot for the generator and the rubber gasket on the air intake housing cover are correctly sealed.

Fig. 30 Showing angle of drive pinion slot when installing distributor. 1965-66 1500 & All 1600

STARTER, REPLACE

1. Disconnect negative battery cable.
2. Disconnect battery cable and cables to generator and ignition switch at terminal No. 30 of starting motor.
3. Disconnect control cable to starting switch at terminal No. 50 at starting motor.
4. Unfasten starter from transmission case and lift it off.
5. When installing lubricate starter shaft bushing with multi-purpose grease. Apply VW Sealing Compound D2 between intermediate bracket and transmission case. Make sure all terminals are tight.

IGNITION SWITCH, REPLACE

1. Disconnect battery ground cable.
2. Remove protective cover behind instrument panel.
3. Disconnect one cable at cable connector, one cable at speedometer and two cables at fuse box and pull all cables through body.
4. Remove two screws and take out ignition switch (steering lock need not be removed).
5. Reverse procedure to install, being sure that lug on switch engages in groove on steering lock.

Fig. 31 Generator properly installed. 1965-66 1500 & All 1600

FUEL INJECTION

1968 Fastback & Squareback Sedans

The electronic fuel injection system is shown schematically in Fig. 32, while Fig. 33 is a layout of system components.

CONTROL UNIT

The heart of the system is the electronic control unit. It controls the amount of fuel to be injected according to engine speed, engine load (intake manifold pressure) and engine temperature.

When the ignition is switched on, current is supplied to the control unit via the main relay. The unit also con-

Fig. 32 Schematic drawing of the fuel injection system

Fig. 33 Diagram of fuel injection system components

trols the fuel pump to which current is supplied via the pump relay when the engine is running.

The control unit opens the injector valves electronically in pairs (cylinders 1 and 4 and cylinders 2 and 3). The amount of fuel injected depends upon the length of time the injectors are kept open and is metered according to engine requirements. This is possible because the injectors are under a constant fuel pressure.

Duration of injection is determined by the control unit, the information processed there being fed by sensing devices mounted on the engine. The control unit is mounted in the left air duct and is connected by a cable harness to the sender units.

FUNCTION OF COMPONENTS

1. The pressure sensor controls the basic fuel quantity by measuring intake manifold pressure.
2. The pressure switch controls the fuel enrichment. It is operated by the differential between the intake manifold and ambient air pressure.
3. The temperature sensor in the crankcase and the temperature sensor on the cylinder head control the fuel mixture enrichment for cold starting and the warm-up period.
4. The trigger contacts in the distributor feed a signal to the control unit when and into which cylinder group fuel is to be injected.

Fig. 34 Air supply for fuel injection system

5. The distributor, which was developed especially for the fuel injection engine, houses the normal contact breaker points and the trigger contacts for the cylinders' injectors.

FUEL PUMP OPERATION

The electric fuel pump draws fuel from the tank through a filter and pumps it through a pressure line into the ring main which distributes fuel to the in-

Fig. 35 Fuel injection systems components

Fig. 36 Checking fuel pressure

Fig. 37 Adjusting fuel pressure regulator

Fig. 38 Adjusting throttle valve switch

jectors and also pipes excess amounts of fuel back to the return line. Electromagnetic injectors are connected to the ring main by distributor pipes. A pressure regulator at the end of the ring main maintains a constant pressure of 28 psi.

AIR SUPPLY, Fig. 34

Air for the fuel injection system passes through four pipes attached to the intake air distributor. A pressure switch, pressure sensor, air cleaner and ignition distributor all are connected to the intake air distributor.

A throttle valve on the inlet side of the air distributor is connected by a cable to the accelerator pedal. At idling speed, the throttle valve is fully closed and air passes through an idling circuit into the intake air distributor. An idling air screw controls the amount of air for idling.

At engine temperatures below 120 deg. F, more air is required and comes in through a line leading from the air cleaner into the air intake distributor. An auxiliary air regulator in that line varies the amount of air, meeting requirements which change as engine temperature varies.

SIGNAL SYSTEM OPERATION

Referring to the letters indicated in Fig. 32, the signals perform the following functions:

1. Signal for engine loading is from pressure sensor at "A" and "B".
2. Signal for engine speed and triggering is from the distributor contacts at "C" and "D".
3. Signal for warming up and cold starting is from temperature sensor at "F".
4. Signal for cutting off fuel at deceleration is from the throttle switch at "G".
5. Signal for full load enrichment is from the pressure switch at "H".
6. Signal for cold start enrichment is from starter at "I".
7. "J" is to injectors for cylinders 1 and 4.
8. "K" is to injectors for cylinders 2 and 3.

Fig. 39 Timing marks on fuel injected engine

Fuel Injection Adjustments

Pressure Regulator

1. Remove air cleaner and connect pressure gauge, Fig. 36.
2. Start engine and allow to idle.
3. If necessary to adjust regulator, back off locknut and turn adjusting screw as required to reach a setting of 28 lbs.

Throttle Valve Switch

The throttle valve switch should operate when the throttle valve is opened by 4° from its closed position. Adjust as follows:

1. Close throttle valve completely.
2. Loosen throttle valve switch and turn it until it can be heard to switch.
3. Turn the switch two graduations (4°) in direction of arrow from the mark opposite the cast-on projection at the switching point, Fig. 38.
4. Tighten screws.

Ignition Timing

1. Set breaker gap or dwell angle to specifications.
2. Connect timing light.
3. Loosen clamp screw on distributor bracket so distributor can just be turned by hand.
4. Pull vacuum hose off distributor vacuum unit.
5. Start engine and allow it to idle.
6. Aim timing light at pulley mark and turn distributor until TDC mark, Fig. 39, aligns with crankcase joint.
7. Tighten distributor bracket and reconnect vacuum hose.

Engine Idle Speed

1. Connect tachometer, start engine and allow it to reach operating temperature.
2. Back off locknut on idle adjusting screw and set idling speed and retighten locknut, Fig. 40.

Fig. 40 Adjusting idle speed

Automatic Stickshift Trans-Axle Section

Description

The Automatic Stickshift consists of the torque converter, a fully synchronized three speed transmission and an automatically operated clutch. The power flow passes from the engine via the converter, clutch and gearbox to the final drive, Fig. A1.

The converter performs the functions of the conventional clutch for starting and stopping while the shift clutch serves only for engaging and changing the speed ranges. The converter has an independent oil supply provided by an engine driven pump and a reservoir.

The automatic clutch is operated by a servo which is influenced by intake manifold vacuum. A control valve between intake manifold and servo controls engagement and release of the clutch, Fig. A2. The signal for this is transmitted from an electrical contact in the gear selector lever. When engaging a driving range this contact is closed and the clutch is disengaged. It remains disengaged until the shift is complete and the driver releases the lever, Fig. A3.

A vacuum reservoir insures that one can still shift the lever even though the engine is switched off, or if there is not sufficient vacuum in the intake manifold.

Operation

Starting: To start the engine the selector lever must be moved to "N" (neutral position). A starter lock switch prevents the engine from starting if a driving range is engaged.

Drive Range L: Used only for pulling away on hills with a fully loaded vehicle or when pulling a trailer. Range is from 0-34 mph.

Drive Range 1: Should be used in heavy

1 - Inner shift lever
2 - Gearshift housing
3 - 1st/reverse shift rod
4 - 2nd/3rd shift rod
5 - Gear carrier
6 - 3rd speed gears
7 - 2nd/3rd gear synchronizer rings
8 - 2nd speed gears
9 - 1st speed gears
10 - Operating sleeve for 1st/reverse gear
11 - Reverse gear drive
12 - Retaining ring for pinion
13 - Pinion
14 - Drive shaft
15 - Transmission case
16 - Shift clutch release shaft
17 - Converter housing
18 - Support tube for one-way clutch
19 - Oil seal for converter
20 - Impeller
21 - Stator
22 - One-way clutch
23 - Turbine
24 - 2nd/3rd gear operating sleeve
25 - 2nd/3rd gear spacer spring
26 - Magnetic oil drain plug
27 - 1st gear synchronizer ring
28 - Synchronizer hub 1st/reverse gear
29 - Differential pinion
30 - Differential side gear
31 - Shift clutch release bearing
32 - Diaphragm spring
33 - Pressure plate
34 - Clutch plate
35 - Carrier plate
36 - Oil seal for converter housing
37 - Bearing for turbine shaft
38 - Turbine shaft
39 - Torque converter

Fig. A1 Automatic Stickshift Trans-Axle

Fig. A2 Automatic clutch hydraulic and vacuum systems

town traffic, medium hills, in slow moving traffic or when rapid acceleration is needed. Range is from 0-56 mph.

Drive Range 2: This is the normal driving range for use on open road at cruising speed and for low to medium speeds in free flowing town traffic. In this range shifting gears is not necessary. Range is from 0 to maximum speed.

Reverse: To engage reverse the selector lever must be depressed while pushing forward.

NOTE: Temperature switches are incorporated which will cause a warning light in the speedometer to light when the converter fluid exceeds permissable temperature. Should this light go on it is an indication to shift the transmission to the next lowest speed range. Higher engine speeds and therefore reduced converter load and faster fluid circulation will lower the temperature and the light will go out.

CONSTANT VELOCITY JOINTS

Description

Vehicles using the Automatic Stickshift are also equipped with a new type rear axle known as a double joint axle.

Both the drive shafts of the new axle have two joints, one on the transmission case and one on the wheel. The joints are all of the constant velocity sliding type, Fig. A4. All movements which take place between joint flange on differential and wheel shafts are compensated for by the constant velocity joints. The grooves in which the balls move inside the joint are arranged in such a way that, together with the torque effective on the shaft, all variations in length are taken up by the joints and the shaft remains in the correct location.

Removal

1. Remove socket head drive shaft bolts, Fig. A5, tilt shafts downwards and remove.
2. Loosen dust seal clips and slide back dust seal.
3. Remove snap ring from ball hub.
4. Drive cap off with a drift. *Do not tilt ball hub more than 20° or the balls may fall out.*
5. Slide outer part with balls on to the ball hub.
6. Support hub and press drive shaft out of ball hub. Remove dished washer.
7. Reverse the removal procedure to install, being sure that the large diameter of the outer part of the joint points to the dust seal.

Rear Wheel Bearing

Removal

1. Loosen castle nut on rear wheel

Fig. A3 Automatic clutch electrical circuit

spline.

IMPORTANT: Accidents are liable to be caused if these nuts are loosened or tightened with the vehicle raised on a lift. It is therefore recommended that these nuts be loosened or tightened with the vehicle on the ground.

2. After loosening castle nut, raise vehicle and remove drive shafts and cover constant velocity joints with plastic covers.
3. Remove castle nut and pull brake drum off.
4. Detach brake line and hand brake cable.
5. Remove backing plate.
6. Mark position of spring plate and diagonal arm at top and bottom with a chisel.
7. Remove lower shock absorber bolt.
8. Remove bolts holding diagonal arm to spring plate and Allen-head bolt securing diagonal arm to bracket and take arm off.

Fig A4 Constant velocity joint

Disassembly

1. Knock rear wheel shaft out with a rubber hammer.
2. Remove spacer ring and roller bearing inner ring.
3. Knock outer ring out with a drift and pry out inner oil seal.
4. Remove snap ring and pull bearing with VW 771.
5. Press rubber bushing out of arm.
6. Press oil seal out of cover.

Reassembly

Reverse disassembly procedure to assemble the unit.

TRANS-AXLE, REPLACE

1. Disconnect ground strap at battery.
2. Remove engine as outlined in the *Engine and Clutch Section.*
3. Disconnect gearshift rod coupling.

Fig. A5 Removing drive shaft bolts

Fig. A7 Transmission assembly exploded

Fig. A6 Torque converter retainer installed

Fig. A8 Removing pinion bearing retaining nut with special wrench

Fig. A10 Removing joint flange caps

Fig. A9 Rear axle assembly exploded

Fig. A11 Removing joint flanges

4. Remove drive shaft screws Fig. A5 and remove drive shafts completely.
5. Disconnect oil hoses, thermo switch connections and starter cables.
6. Disconnect clip for vacuum hoses at clutch servo and pull off hose.
7. Push back rubber cap and pull three-pin plug off neutral safety switch on gearshift housing. Remove nuts at front transmission mounting.
8. Attach retainer for torque converter, Fig. A6. (Fabricate strap).
9. Support transmission with a suitable jack, remove screws at rear transmission mounting and withdraw transmission from vehicle.
10. Reverse the removal procedure to install the assembly, noting the following.
    a. Be sure the slot in the plug and lug on the switch are aligned properly.
    b. Clean flanges of rear wheel shafts. There must be no grease between the contact surfaces of the joints at the flanges.

TRANS-AXLE, OVERHAUL

Transmission Disassembly Sequence Fig. A7

The following sequence of operations is recommended by Volkswagen when disassembling the trans-axle. When reassembling, reverse the procedure and observe the remarks which follow this sequence. Before removing the differential, the transmission gears must be removed.

1. Remove gearshift housing and inner transmission lever.
2. Remove nuts at gear carrier.
3. Remove transmission cover and gasket.
4. Remove lock and back off pinion bearing retaining nut until it just contacts the ring gear. Fig. A8.
5. Press out transmission until retaining nut contacts the case again then alternately loosen the retaining nut and press out transmission until the nut has been completely screwed clear of the bearing. Press out bearing completely with transmission and remove. Note thickness of shim "S3" Fig. A19, for drive pinion adjustment. If no parts directly effecting the drive pinion adjustment are replaced during repairs, the old shims must be inserted again when assembling.
6. Clamp transmission at gear carrier in a vise or install it in selector fork adjustment device (VW492a) and remove selector fork for first and reverse gear.
7. Pull second and third selector shaft out of selector fork.
8. Remove snap ring and dished washer from main drive shaft. *Use caution as the dished washer is pretensioned.*
9. Press out main drive shaft.

Rear Axle Disassembly Sequence Fig. A9

1. Remove transmission and gears.
2. Pierce caps of joint flanges with a screwdriver and remove caps. Fig. A10.
3. Remove snap ring and carefully pry out joint flanges. Fig. A11.
4. Remove lock plates and carrier bearing rings. Fig. A12.
5. Lift differential and ring gear out of case and remove spacer rings.

Fig. A12 Removing carrier bearing rings

Differential Repairs

Disassembly Fig. A13

1. Remove ring gear bolts and press ring gear off housing.
2. Press cover from housing and take out side gear with thrust washer.
3. Press carrier bearing from differential cover and housing.
4. Drive out pin and shaft. Remove differential pinions and side gear.

Reassemble

Reverse the disassembly procedure to assemble the unit, noting the following.

1. When installing differential pinions, use a new roll pin and peen at both ends.
2. Be sure all surfaces between ring gear and cover are clean, and free of burrs and pressure marks.
3. Tighten ring gear bolts diagonally opposite.

IMPORTANT: If ring gear and pinion are to be replaced, a new selective spacer must be used to reset pinion depth.

Fig. A13 Differential assembly exploded

Fig. A14 Pressing main drive shaft and pinion into gear carrier

Fig. A15 Main drive shaft parts

Adjusting Drive Pinion & Ring Gear

The ring gear and drive pinion are a matched set and must be replaced as such. If the gear set is not to be replaced, the existing "S3" pinion depth shim Fig. A19 should be retained to preserve the original pinion setting. If, however, the gear set is replaced, the pinion depth must be reset by the use of a new "S3" shim. The size of the new shim can be calculated by comparing the pinion markings "r" plus shim sizes to duplicate the original pinion depth.

The ring gear must be reset whenever work is done on the differential assembly or its original position is disturbed.

The ring gear is adjusted for bearing pre-load and gear backlash through the use of threaded carrier bearing rings. These rings are screwed in or out to change the lateral position of the ring gear once the pinion depth has been established. Ring gear carrier bearing preload is established by first screwing the ring on the ring gear side of the housing in until the outer edge is .006″ below the measuring surface of the case. The other ring is then installed on the opposite side and turned in until the force required to turn the ring gear reaches 16-20 in. lbs. for new bearings. This is measured by turning the ring gear side of the differential assembly with a torque wrench while tightening the opposite side ring.

The ring gear backlash is then adjusted by loosening one side ring while tightening the opposite side *an equal amount*. This is critical, as any change in the relationship of the rings to each other will change the preload. Adjust the ring gear until a backlash of .006-.009″ is obtained.

IMPORTANT: In view of the foregoing remarks, it can be seen that any major repairs on the rear axle, call for most accurate and precise adjustment. If the necessary tools and equipment designed for this work are not available to do the job, the work should be farmed out to a Volkswagen service station or other establishment having the facilities to do the work properly.

Transmission Installation Sequence

1. Engage selector fork for 2nd and 3rd gears in the operating sleeves.
2. Position pinion, main drive shaft and gear carrier under press Fig. A14 and press onto the main drive shaft. Guide main drive shaft and pinion carefully in order to avoid damage to the splines. Also, be sure that the selector fork for the 2nd and 3rd gear is correctly positioned.
3. Slide spring washer onto the main drive shaft, install new lock ring and press down until it snaps into the groove. Squeeze lock ring with pliers to be sure it bottoms correctly in the groove.
4. Install and adjust shift forks.

NOTE: The shift forks can only be set properly with the aid of setting fixture VW294a. During adjustment, the pinion and main drive shaft must be in the exact position as they will be when installed in the transmission case. To achieve this, the shims "S3" (or pinion depth) must be determined beforehand and placed in the setting fixture as well.

5. Install gear carrier, pinion with shim and drive shaft in setting fixture and secure with four nuts.
6. Screw retaining ring on to double taper roller bearing and hand tighten with "C" wrench VW 183.
7. Push shift rod into 2nd and 3rd gear fork and install clamp screw.
8. Install shift fork for 1st and reverse gears and insert clamp screw.
9. Place 1st and reverse shift rod into the detent groove for 1st and slide the operating sleeve and fork over the synchro teeth until it is against the 1st speed gear. Centralize the fork in the operating sleeve groove and tighten the clamp screw.

NOTE: The shift forks must not rub on the sides of the groove in the sleeve when in neutral or when a gear is engaged.

Fig. A16 Checking synchronizer rings for wear

10. Select both gears and neutral several times while turning transmission and check clearance between fork and sleeve groove in each position. When uniform clearance has been established, at each side of the groove, tighten the clamp screw to 18 lb. ft.
11. Place 2nd and 3rd shift rod into the detent groove for 3rd gear. Adjust as for 1st and reverse and tighten clamp screw to 18 lb. ft.
12. Check interlock mechanism to be sure that when one gear is engaged it is not possible to engage any other gear.
13. Insert transmission and gasket into the transmission case and use a rubber hammer to drive in the pinion and main drive shaft.

NOTE: If the differential and ring gear are still installed in the case as the transmission is being installed the retaining nut of the tapered roller bearing must be inserted and screwed on while the transmission is being driven in.

14. Tighten tensioning nut to 87 lb. ft. with special wrench VW 183. Tighten gear carrier nuts diagonally. Insert retaining nut lock plate and tighten screws.
15. Insert gearshift housing with transmission shift lever and tighten nuts.
16. Install transmission cover with gasket and tighten screws diagonally.

Main Drive Shaft Repairs Fig. A15

Disassemble

1. Remove thrust washer, 3rd gear, needle bearing and synchronizer stop ring.

Fig. A17 Etched marks must be aligned when assembling clutch gear

Fig. A18 Springs assembled over clutch keys

Fig. A19 Drive pinion parts

2. Press off inner race of needle bearing, clutch gear with operating sleeve and 2nd gear.
3. Remove woodruff key and disassemble synchronizer hub.

Inspection

1. Check gears, particularly clutch toothing, operating sleeve, thrust washer, main drive shaft, clutch gear, needle bearings, race rings and woodruff key for wear and damage. Replace if necessary.
2. Press synchronizer stop rings onto gears and measure clearance between gear and ring. Dimension A Fig. A16. If the clearance exceeds .067″, the ring must be replaced.

Reassembly

Reverse disassembly procedure to reassemble the unit, noting the following.

1. Install 2nd speed gear, needle bearing and synchronizer stop ring.
2. Install woodruff key.
3. When assembling clutch gear for 2nd and 3rd gears, take care to align the etched marks. Fig. A17. Operating sleeve and clutch gear are matched and must be replaced in pairs only.
4. Position spring rings on clutch gear assembly so they are angled 120° offset from each other Fig. A18. Be sure to fully engage the spring ends over the clutch keys.
5. Press clutch gear assembly onto shaft.
6. Heat inner race of needle bearing for 3rd gear to about 200°F before pressing onto shaft.
7. Install needle bearing gear, synchronizer stop ring and thrust washer for 3rd gear.

Drive Pinion Repairs Fig. A19

Disassemble

1. Remove snap ring and press off 3rd speed gear and needle bearing inner ring.
2. Remove spacer spring and 2nd gear snap ring.
3. Remove 2nd speed gear, 1st speed gear with synchronizer ring, needle bearing, synchronizer hub with operating sleeve and shim.
4. Using special wrench VW 293, unscrew round nut.
5. Press off pinion bearing.
6. Remove operating sleeve, clutch keys and spring from synchronizer hub.

Inspection

1. Check pinion, tapered bearing, needle bearing and rings, gears, clutch keys and synchronizer hub for wear or damage.
2. Check synchronizer teeth on gear, synchronizer ring and operating sleeve.
3. Press synchro ring over cone on gear and measure dimension "A" Fig. A16. If clearance exceeds .067″, the synchro ring must be replaced.
4. If necessary to replace either 2nd or 3rd speed gear, these must be replaced in pairs.

Reassemble

Reverse disassembly procedure to assemble the unit, noting the following.

Fig. A20 Drive pinion dimensions

1. Before being pressed onto the pinion, the inner rings of the double taper roller bearing should be heated to about 200° F.
2. Install new round nut and tighten to 145 lb. ft. in fixture VW 293.
3. Stake locking shoulder of round nut into pinion splines 120° apart using blunt chisel. Inspect the shoulder at this point to be sure it is not cracked or burred.
4. To find thickness of shim for round nut, use this formula A-B + shim= X. Fig. A20. Dimension X is measured from tapered roller bearing *inner* race to shim and includes shim thickness. Select fit shim to make dimension X=1.75″ with a tolerance of .002″.
5. Assemble pinion up to 2nd speed gear. Install a select fit snap ring to give a clearance of .001-.010″ between gear and snap ring with the smaller dimension desired.
6. Fit spacer spring and 3rd speed gear
7. Heat needle bearing inner ring to 200° F and press it on with 3rd speed gear.
8. Fit snap ring.

Fig. A21 Shift clutch exploded

Fig. A22 Centering clutch plate with pilot shaft

Shift Clutch Fig. A21

Removal

1. Pull torque converter off one-way clutch support tube and remove. Seal off hub opening.
2. Remove clutch operating lever. Remove nuts between clutch housing and transmission case. Two are accessible from the differential housing after the transmission cover has been removed.
3. Pull transmission off the studs of the clutch housing and remove it. Turn the clutch lever shaft so that the jaws disengage from the release bearing. Remove both lower engine mounting bolts.
4. Remove clutch disc and pressure plate.

Installation:

1. Coat release bearing guide on transmission case neck and both lugs lightly with lithium grease and insert bearing into clutch.
2. Center clutch plate with a pilot shaft and tighten clutch bolts evenly. Fig. A22. Use caution to be sure the release bearing is properly located in the diaphragm spring.
3. Insert lower bolts for engine mounting from the front. Check stud sealing rings and replace if necessary.
4. Push transmission onto the converter housing studs. Insert clutch lever shaft behind the lugs of the release bearing and push the release bearing onto the transmission case neck. Tighten nuts evenly.
5. Install clutch operating lever and adjust clutch.
6. Push torque converter onto the one way clutch support tube and insert into the turbine shaft by turning.

4-Speed Trans-Axle Section

DESCRIPTION

The transmission, rear axle and engine are a unit. The rear axle is the swing half-axle type. The rubber cushioned transmission case is secured to the frame at three points and incorporates the transmission, final drive and differential, Fig. 1.

The transmission case is of tubular construction with an integral clutch housing and engine mounting flange at one end and gear carrier and gearshift housing attached at the other end. Two final drive covers with ball-shaped surfaces are provided for mounting the rear axle tubes.

The transmission has four forward speeds and one reverse. Synchromesh is obtained with all forward speeds which are in constant mesh for quiet operation.

The shifting rod in the frame tunnel links the transmission to the gearshift lever. The synchronizers are located on the drive pinion for 1st and 2nd, and on the main drive shaft for 3rd and 4th speeds.

The transmission gears and differential are combined in the transmission case and are both lubricated with the same gear oil. The oil capacity is 5.3 pints.

REAR AXLE, REPLACE

NOTE: If the rear axle is to be disassembled upon its removal from the car, loosen the axle shaft nuts before raising the vehicle.

REMOVAL

1. Disconnect battery ground strap.
2. Raise and support vehicle on jack stands and remove engine as outlined in the *Engine & Clutch Section.*
3. Remove rear wheels.
4. Disconnect brake hoses at rear.
5. Disconnect brake cables at emergency brake, remove hand brake and pull cables from conduits.
6. Loosen dust sleeves.
7. Remove shock absorber lower mounting bolts.
8. With a chisel, mark the position of the spring plate in relation to the axle shaft bearing housing in line with the groove in the bearing housing.

Fig. 1 Transmission and rear axle assembly. The transmission is housed in a one-piece case and is synchronized in all forward gears

Fig. 2 Rear axle shaft details (typical)

Fig. 4 Clearance between flat end of axle shaft and side gear should be .0012-.004"

9. Remove rear axle shaft bearing housing bolts.
10. Disconnect clutch cable from clutch operating shaft lever. Slide off rubber boot and remove cable and sleeve from bracket on left-hand final drive cover.
11. Unhook accelerator cable from gear carrier.
12. Disconnect cables from starter.
13. Remove inspection cover under rear seat and remove screw at rear of shifting rod coupling. Move shift lever to withdraw coupling from transmission shift rod.
14. Remove nuts from cushions at front of transmission case.
15. Push a roller jack under vehicle and clamp a suitable cradle (VW-609) to rear axle.
16. Remove two bolts at transmission carrier. Then roll rear axle from under car.

INSTALLATION: Reverse the removal procedure to install the assembly, noting the following:

1. Grease the two transmission carrier mounting bolts and tighten them.
2. Tighten mounting plate nuts at front of transmission case.

IMPORTANT: When installing a new rear axle the nuts that attach transmission carrier to rear rubber cushions should be loosened and tightened after nuts of front rubber cushion have been tightened. This procedure applies also when the transmission carrier has been removed. This tightening sequence is recommended to avoid distortion and premature wear of rubber cushions.

---

3. When lowering the rear axle, do not allow main drive shaft to strike floor.
4. Be certain that points on the coupling screws are seated in their recesses. Secure each screw with wire.
5. Hook accelerator cable to retainer on gear carrier.
6. Adjust rear wheels and tighten spring plate mounting bolts to 72-87 ft-lbs.
7. Tighten shock absorber lower mounting bolts.
8. Examine splines in hub of brake drum; if worn or damaged, replace drum.
9. Adjust clutch pedal free play after engine is installed.
10. Torque rear axle nuts to 217 ft.-lbs.
11. Bleed and adjust brake system.

Fig. 3 Location of differential side gear lock ring

REAR AXLE, OVERHAUL

Disassembly Sequence

The following sequence of operations is recommended by Volkswagen when disassembling the rear axle. When reassembling, however, reverse the procedure and observe the remarks which follow this sequence.

1. Mount rear axle in a suitable fixture (VW-307).
2. Remove drain plugs and drain unit.
3. Remove starting motor.
4. Remove axle shaft nuts and brake drums.
5. Remove brakes and back plates.
6. Remove rear axle tubes and shafts.
7. Remove gearshift housing.
8. Remove differential.
9. Remove rear main drive shaft.
10. Remove transmission.
11. Remove reverse drive gear and shaft.

Fig. 5 Clearance between fulcrum plates and side gears should be .0014-.0096"

Fig. 6 Installing differential side gear, axle shaft and thrust washer

12. Remove main drive shaft and drive pinion from gear carrier.
13. Remove selector shafts and detent balls and springs.

Rear Wheel Bearing & Oil Seal

REMOVAL

1. Remove axle shaft nut and brake drum, Fig. 2.
2. Remove screws and take off cover and oil seal.
3. Remove brake backing plate.
4. Remove outer spacer, gasket, washer and cover gasket.
5. Use a suitable puller to remove bearing, and take off inner spacer (VW-241 and VW-202k).

INSTALLATION

1. Use new gaskets.
2. If any signs of unevenness are visible on the lip, the oil seal should be replaced. Press the old seal out of the cover. Lightly coat the new seal with oil and press it into the cover.
3. Check and replace the outer spacer if it is scored, cracked or rusted.
4. To avoid damage to the oil seal lip by friction, the spacer should be lightly coated with oil.
5. Install cover so that oil drip nose points downward.
6. Make certain that oil drip tube bears tightly against brake drum to prevent oil from fouling brake shoes.
7. Tighten axle shaft nut to 217 ft-lbs and secure with cotter pin.
8. Check and replenish transmission oil level.
9. Bleed and adjust brakes.

Fig. 8 Installing gearshift housing

Rear Axle Tubes & Shafts

REMOVAL

1. Remove brake drum, bearing cover, brake backing plate and wheel bearing.
2. Remove nuts and withdraw axle tube and retainer. Take off gasket and plastic packing.
3. Remove differential side gear lock ring, Fig. 3.
4. Remove side gear thrust washer and axle shaft.
5. Remove side gear and fulcrum plates from housing.
6. Drive out lock pin in axle shaft bearing housing.
7. Loosen dust sleeve.
8. Press axle tube from bearing housing. If bearing housing is damaged during pressing operation, replace it with a new one.
9. Remove dust sleeve from axle tube and take off axle tube retainer.

INSTALLATION: Reverse the procedure to assemble, observing the following:

1. Before pressing bearing housing into place, clean and oil all seating surfaces.
2. Clearance between flat end of axle shaft and inner diameter of differential side gear should be .0012-.004", measured across the ball-shaped sides, Fig. 4. If clearance is excessive, replace with a new axle shaft and side gear set. Excessive clearance can lead to rear axle noise.
3. Check axle shaft run-out at ball bearing seat. If found to be in excess of .002", straighten axle shaft cold in a press or install a new one.
4. Check clearance between axle shaft fulcrum plates and differential side gears, Fig. 5. If excessive clearance is present, install oversize fulcrum plates or replace worn parts.
5. Install differential side gear, axle shaft and thrust washer in differential housing and install lock ring, Fig. 6.
6. Axle tube should be installed without end play by selecting a tube retainer gasket of appropriate thickness. Tighten retainer nuts to 14 ft-lbs.
7. Dust sleeve clips should not be tightened until after axle shaft is installed to prevent sleeves from being twisted and subsequently damaged.

Rear Axle Dust Sleeve

NOTE: To avoid removal or disassembly of rear axle when renewing a damaged sleeve, a split type dust seal is available, Fig. 7.

1. To remove damaged sleeve, take off both clips and cut off damaged sleeve. Clean axle tube and retainer.
2. To install, lightly coat joining faces of split type sleeve with sealing compound. The joining faces should point to rear as shown in Fig. 7.

Fig. 7 Installing split type rear axle dust sleeve

NOTE: Dust sleeve screws and retaining clips should not be over-tightened. Tighten screws and clips with rear axle under load (car wheels on floor).

TRANSMISSION CASE

Transmission Carrier

1. Remove attaching screws and take off carrier.
2. Remove nuts attaching rubber cushions to transmission case and take off cushions.
3. To install, tighten carrier attaching screws *but only after the transmission is installed and front rubber cushion screws are tightened.*

Gearshift Housing

1. Remove gearshift housing rubber cushion. Unfasten and remove gearshift housing and transmission shift lever. Remove gasket and clean joining faces.
2. If shift lever bushings require replacement, ream new bushings (when installed) to .5918-.5925".
3. Make sure selector shafts are in neutral position when attaching gear-

Fig. 9 Removing final drive cover with puller (VW297)

Fig. 10 Pressing out differential

shift housing, Fig. 8. Tighten nuts to 14 ft-lbs.

4. Check rubber cushion for damage. If cushion is replaced, rear wheels have to be re-adjusted.

Differential & Transmission

REMOVAL

1. Remove gearshift housing.
2. Pry off lock plates for drive pinion and main drive shaft nuts.
3. Lock transmission by engaging reverse and 3rd gear.
4. Remove drive pinion and main drive gear nuts and take off lock plates. Discard lock plates.
5. Remove gear carrier stud nuts and take off ground strap and accelerator cable retainer.
6. Remove nuts from studs on left-hand final drive cover.
7. Remove final drive cover, Fig. 9. The thrust plate of the tool is positioned on differential housing flange and spindle is attached to axle tube retainer studs.
8. Position spindle and thrust plate of tool shown in Fig. 9 on right-hand final drive cover and press out differential, Fig. 10.

IMPORTANT: When removing differential, make note of thicknesses and arrangement of shims present to facilitate reassembly.

Fig. 12 Removing snap ring and reverse drive gear

9. Loosen retaining ring for reverse gear on mainshaft, slide reverse gear rearward and screw main drive shaft apart.
10. Remove reverse gear and retaining ring and withdraw mainshaft toward the rear, taking care not to damage oil seal.
11. Remove right-hand final drive cover.
12. Remove drive pinion bearing retainer.
13. Push transmission out of case, Fig. 11. *In order to facilitate reassembly note quantity and thickness of pinion shims present.*
14. Remove snap ring and reverse drive gear, Fig. 12.
15. Remove woodruff key and pull reverse gear shaft and thrust washer from case.
16. Remove screw securing spacer sleeve for reverse gear shaft needle bearings. Then drive out needle bearings, Fig. 13.
17. Remove screw securing needle bearing on main shaft. Then drive out needle bearing.
18. Press bearing from left and right final drive covers.
19. Remove clutch release bearing and operating shaft.

INSTALLATION: Clean and inspect all parts, replacing any that are damaged. When installing, observe the following remarks:

1. Check clutch operating shaft for free movement, if necessary, apply grease to shaft.
2. Install reverse gear shaft needle bearings and spacer sleeve.
3. Install main shaft needle bearing.
4. Install reverse shaft with thrust washer and drive gear over woodruff key and secure with snap ring.
5. Place drive pinion shims over bearing and screw two 4″ studs into bearing retainer to prevent retaining ring from turning when transmission is installed, Fig. 14.
6. Push reverse selector fork and sliding gear onto reverse lever and engage reverse gear.
7. Install transmission into case. If necessary, use a rubber mallet to position pinion correctly in bearing seat. Use a new gear carrier gasket. Tighten bearing retainer screws to 36 ft-lbs, and use new lock plates.
8. Lubricate lip of oil seal before installing rear half of main shaft. Screw both halves of main shaft together. Back them off until reverse gear splines are in line. Make sure that reverse gear snap ring tension is correct.
9. Press bearings into left and right final drive covers.
10. Using a new gasket, install right-hand final drive cover. Tighten nuts to 14 ft-lbs.
11. Install differential in transmission case, being sure that shims are inserted correctly, Fig. 15.
12. Tighten rear carrier stud nuts to 14 ft-lbs.
13. Engage reverse and 3rd speed gear to prevent transmission from turning. Then tighten main shaft nut to 87 ft-lbs. Back nut off and re-tighten to 36 ft-lbs and secure with new lock plates.
14. Tighten drive pinion nut to 22 ft-lbs and secure with new lock plate.
15. When attaching gearshift housing, be sure that the three selector shafts are in neutral position.

Fig. 11 Pushing transmission out of case with Tool VW296

Gear Carrier

DISASSEMBLE

1. Remove reverse selector fork with sliding gear from reverse lever.
2. Remove shims from drive pinion bearing, noting the thickness of shims present to facilitate reassembly.
3. Mount gear carrier in vise, Fig. 16, and loosen shift fork lock screws. Remove 1-2 selector fork.
4. Pull out 3-4 selector shaft from its fork.
5. Place a rubber band around 1-2 gear operating sleeve and mainshaft.
6. Mount assembly in a press as shown, Fig. 16. Apply force to mainshaft to remove transmission gears from gear carrier. Drive pinion should be guided carefully to avoid tilting which would lead to damage to gears and needle bearings.
7. Remove screw that secures drive pinion needle bearing and press out bearing.

Fig. 13 Driving out reverse gear shaft needle bearings

Fig. 14 Showing use of guide studs to prevent retaining ring from turning when installing transmission

Fig. 15 Installing differential into transmission case. Make sure shims are installed correctly

Fig. 16 Pressing transmission gear assembly from gear carrier

8. Press ball bearing from mainshaft.
9. Place gear carrier in vise and remove reverse lever guide screw, Fig. 17.
10. Pull out reverse gear selector shaft and remove reverse lever guide.
11. Pull out 1-2 selector shaft and remove reverse lever from support.
12. Remove 3-4 selector shaft.
13. Remove plungers and detent balls. Then remove springs with screwdriver, Fig. 18.

NOTE: If it becomes necessary to remove the reverse lever support, the dimensions indicated in Fig. 19 should be present. Check the reverse lever for proper position when adjusting selector forks. The lock nut should be tightened to 25 ft-lbs.

REASSEMBLE: Clean all parts and replace those that are damaged. Check the detent springs. Free length of springs are 1", wear limit 0.9". If difficult shifting is experienced, check the force of the springs with the drive pinion and mainshaft removed. The force applied to overcome detent ball grooves in the selector shafts should be 33 to 44 lbs.

1. Insert detent springs through holes in selector shafts. Inasmuch as the top halves of detent spring bores are not bushed, the 1st, 2nd and reverse springs can more easily be installed into the top halves first.
2. Install reverse selector shaft with reverse lever and its guide.
3. Install 1-2 and 3-4 speed selector shafts along with two interlock plungers. Engage a gear to check for correct interlocking. The selector shaft next to the one used must be locked. When engaging 1st and 2nd gears the other two selector shafts should be locked.
4. Install drive pinion needle bearing.
5. Place carrier in a press and press mainshaft ball bearing into position.
6. Check selector forks for wear. If clearance between forks and operating sleeves are beyond the limits of .004-.012", replace worn parts.
7. Position 3rd and 4th gear selector fork before pressing transmission into gear carrier. When pressing, the drive pinion should be lifted slightly and care should be exercised to see that the installed selector fork is not jammed on the selector shaft. Fully insert the shaft into the fork beforehand.

NOTE: When pressing transmission into position, wrap a strong rubber band around the assembly as shown in Fig. 20 to hold the drive pinion and mainshaft together.

8. Install 1-2 selector fork.
9. Attach reverse selector fork with reverse sliding gear on reverse lever.
10. Adjust selector forks.

Selector Forks, Adjust

NOTE: Proper adjustment of the forks can only be accomplished with the special Gear Shift Test Tool VW-294. Since the adjustment of the 1-2 and reverse forks

Fig. 17 Removing reverse lever guide screw

Fig. 18 Removing detent springs with screwdriver

Fig. 19 Correct reverse lever support position. Dimension "A" is 1.520", "B" is 0.40"

Fig. 20 Pressing transmission gear assembly into gear carrier. Note heavy rubber band around gear assembly to hold drive pinion and mainshaft together

Fig. 21 Gear carrier mounted in Tool VW294

Fig. 22 Gearshift housing mounted in Tool VW294

alters in accordance with the adjustment of the drive pinion, the drive pinion adjustment must be made beforehand. Aside from that the drive pinion and mainshaft nuts must be tightened beforehand to the specified torque. The equipment needed is shown in use in Figs. 21 and 22.

1. Place transmission with drive pinion shims and gear carrier gasket on Tool VW-294 and attach gear carrier with four screws, Fig. 21.
2. Tighten drive pinion ball bearing retainer with two screws installed diagonally to 36 ft-lbs.
3. Push crank of tool onto splines of mainshaft so that mainshaft is locked by crank handle. Engage 1st and 2nd gears.
4. Tighten mainshaft nut to 87 ft-lbs. Then loosen nut and re-tighten to 36 ft-lbs.
5. Tighten drive pinion nut to 22 ft-lbs.
6. Attach gearshift housing and shift handle, Fig. 22. By attaching gearshift handle, a proper seating of the mainshaft ball bearing in gear carrier is assured.
7. Set 1-2 and 3-4 selector forks so they are moving freely in operating sleeve, not only in neutral position but also when different gears are engaged.
8. Set reverse gear selector fork so that reverse sliding gear is centered between operating sleeve and mainshaft 2nd gear with 2nd gear engaged, and properly engaged in reverse gear on drive pinion with reverse gear engaged.
9. Selector fork lock screws should be tightened to 18 ft-lbs, using a T-handled torque wrench as shown in Fig. 22. Tighten reverse lever guide screw to 14 ft-lbs.

Mainshaft Oil Seal, Replace

1. Remove engine, clutch release bearing and damaged oil seal, Fig. 23.
2. When installing, lightly coat exterior of new seal with sealing compound. Oil mainshaft and oil seal lip.
3. Slide seal on mainshaft and drive it in position with a suitable driving sleeve (VW-244b). Use care to see that spring around seal lip is securely in place, Fig. 24.

Fig. 23 Removing mainshaft oil seal

Fig. 24 Installing mainshaft oil seal

DRIVE PINION REPAIRS

DISASSEMBLE

1. Press needle bearing inner race and 4th gear off shaft.
2. Remove 4th gear woodruff key and strip pinion of loose parts, Fig. 25.

1 - Shim
2 - Drive Pinion
3 - Woodruff key for 4th gear
4 - Ball bearing
5 - Thrust washer for 1st gear
6 - Needle bearing inner race (1st gear)
7 - Needle cage (1st gear)
8 - Thrust washer for needle bearing (1st gear)
9 - Round nut
10 - Shims, end play 1st gear
11 - Ball bearing retainer
12 - 1st gear
13 - Synchronizer stop ring (1st gear)
14 - Clutch gear for 1st and 2nd gears, and reverse gear
15 - Synchronizer stop ring (2nd gear)
16 - 2nd gear
17 - Needle cage (2nd gear)
18 - 3rd gear
19 - Concave washer
20 - Shims for concave washer.
21 - Spacer sleeve
22 - 4th gear
23 - Inner race, needle bearing in gear carrier

Fig. 25 Drive pinion disassembled

Fig. 26 When installed, bearing numbers on both races should be exactly opposite to one another to avoid noisy bearing operation

Fig. 27 First gear end play at "A" should be .004-.010"

Fig. 28 Dial gauge and associated tools (VW299) used to check concave washer adjustment

3. Then press off inner race of needle bearing, 1st gear thrust washer and ball bearing.

INSPECTION

1. Inspect all parts for wear or damage. If drive pinion is to be replaced, a matching ring gear and pinion should be used. Note the matching number on pinion and ring gear.
2. If drive pinion or ball bearing are to be replaced, the pinion and ring gear must be re-adjusted.

Fig. 29 Main drive shaft disassembled

3. Whenever a damaged gear must be replaced, the mating gear must also be replaced. Worn or damaged 1st and 2nd gears require the replacement of the front mainshaft.
4. If a gear will not engage even though clutch is fully released, it may be due to the teeth of the synchronizer stop ring being too much out of line with the splines of the operating sleeve. This condition is caused by worn stop ring slots.
5. Check the clearance between synchronizer stop ring face and clutch teeth of the corresponding gear (normal .043"). If the wear limit of 0.24" is reached the stop ring should be replaced. Premature wear of stop rings is due to clutch in bad condition.

REASSEMBLE: Reverse disassembly procedure to assemble the unit, noting the following remarks:

1. Before pressing onto pinion, inner races of ball bearing and needle bearing inner race of 1st gear should be heated in an oil bath to 194°.
2. Slide one inner bearing race onto pinion. Slide on ball bearing, then second inner race so that bearing numbers on both races are exactly opposite one another, Fig. 26.
3. Slide 1st gear thrust washer and needle bearing inner race onto pinion.
4. Mount assembly in a press and press all parts in position. Tighten round nut to 87 ft-lbs.
5. After 1st and 2nd gears have been installed, measure clearance between thrust washer and 1st gear ("a"), Fig. 27. Shims are available in several thicknesses for selective fitting.
6. Referring to Fig. 25, assemble remaining parts on pinion. When installing the concave washer it should be adjusted with Tool VW-299 (see below).
7. The 4th gear and needle bearing inner race should be heated in an oil bath to 194° before being pressed into position. Then insert woodruff key and slide 4th gear on pinion with its wide shoulder facing spacer sleeve. Finally press 4th gear and needle bearing inner race into position.

Concave Washer, Adjust

The drive pinion concave washer must be adjusted to provide a spring travel of .007" (plus or minus .0004"). This washer exerts a pressure of about 200 lbs on the 3rd gear and the 1-2 clutch gear and also reduces oscillations of these parts which are fitted to the drive pinion with a minimum backlash of .002". The quiet running of the rear axle will be affected if the clutch gear and 3rd gear are tightly seated and no backlash is present as a result of the concave washer being too tightly adjusted. If the maximum spring travel is exceeded the 2nd gear will tend to jump out. It is important, therefore, that the equipment shown in Fig. 28 be used to correctly determine the shimming required to adjust the concave washer.

Fig. 30 Check clearance between synchro stop ring face and clutch teeth of corresponding gear at "A"

Fig. 31 Assemble 3-4 speed synchronizer with etched line lined up

MAINSHAFT REPAIRS

DISASSEMBLE, Fig. 29

1. Remove thrust washer, 4th gear, needle cage and stop ring.
2. Remove 4th gear needle bearing inner race, 3-4 clutch gear and 3rd gear by pressing shaft through these parts.
3. Remove needle cage for 3rd gear.
4. Disassemble 3-4 synchronizer.

INSPECTION

1. Check all parts for wear or damage.
2. Suspend front mainshaft between two points and check runout at the contact surface of 3rd gear needle bearing. Runout should not exceed .0006″.

IMPORTANT: If front mainshaft has excessive wear or runout it should be replaced. Since the gears may only be replaced in pairs, the gear for 1st and 2nd speeds on drive pinion must also be replaced.

3. Check clearince between stop ring face and clutch teeth of corresponding gear with a feeler gauge. Normal clearance is .043″. If wear limit of .024″ is reached, replace stop rings.
4. If a gear will not engage, even though clutch fully releases, teeth of stop ring may be too much out of line with splines of operating sleeve. This may be caused by slots in stop ring being worn, Fig. 30.

REASSEMBLE

1. Reverse disassembly procedure to assemble the unit, observing the following:
2. Assemble 3-4 synchronizer unit, being sure etched line on clutch gear and sleeve line up as shown in Fig. 31. To reduce backlash between these parts to a minimum, they are paired and etched for identification. Install shifting plates and position the two snap rings offset to one another, making sure that ends of each ring engage behind the shifting plates.
3. Insert woodruff key for clutch in mainshaft and install 3rd gear synchro stop ring on gear cone.
4. Press 3-4 clutch gear on shaft. The identifying No. 4 on clutch gear must point toward 4th gear. The 3rd gear is lifted slightly and turned until stop ring engages in shifting plates.
5. Press 4th gear needle bearing inner race into position.

DIFFERENTIAL REPAIRS

DISASSEMBLE, Fig. 32

1. Remove lock wire and ring gear screws.
2. Lift off ring gear.
3. Drive out differential pinion shaft with a drift after having removed the pin and remove pinions.

Fig. 32 Rear axle differential

REASSEMBLE

1. Check concave differential pinion contact surfaces in housing for wear and damage. If necessary, replace differential housing.
2. Peen lock pin for differential shaft when unit is assembled.
3. Check ring gear for wear or damage. If necessary, replace with matched set of ring gear and drive pinion.

IMPORTANT: If differential housing or ring gear and pinion is to be replaced, the transmission must be readjusted.

4. Keep contact surfaces of differential housing and ring gear absolutely clean to insure a uniform backlash.
5. Tighten ring gear attaching screws to a torque of 43 ft-lbs.
6. Insert wire so that it imposes a clockwise tension on the screws when twisting its ends.

Adjusting Drive Pinion & Ring Gear

Quiet operation and minimum wear of the final drive depend on the proper adjustment of the ring gear and drive pinion. For this reason, the drive pinion and ring gears are machined in pairs during production, and inspections carried out with special test appliances to ensure correct tooth contact and silent meshing in both turning directions.

Quiet operation is obtained by adjusting the pinion endwise with the ring gear lifted sufficiently out of the fully engaged position (without backlash) to ensure that the backlash is within the prescribed tolerance of .0067″ to .0098″. The tolerance discrepancy from the standard fitting dimension of the drive pinion is measured and marked on the pinion face. Each gear set is given a matching number and replacement must be made in pairs.

It is usually only necessary to re-adjust the ring gear and drive pinion when doing repairs to the rear axle if parts have had to be replaced which directly affect the adjustment. It is sufficient to re-adjust the ring gear if the differential housing, a final drive cover or a differential bearing have been replaced. However, the ring gear and drive pinion must be re-adjusted if the transmission case, the gear set itself or the drive pinion ball bearing have been replaced.

In making the adjustment, the drive pinion must first be adjusted by installing shims between the ball bearing and the contact surface of the transmission case to ensure that the distance from the ring gear center line to the drive pinion face coincides with the fitting dimension determined at the factory. Then the ring gear is adjusted to give the prescribed backlash and the thickness of the shims for the differential housing determined. It is important, however, to note that both final drive covers must be installed with a pre-load of .0055″. After determining the thickness of the shims, a pre-load of .0028″ must be taken into consideration on both sides.

IMPORTANT: In consideration of the foregoing remarks, any major repairs on the rear axle calls for most accurate and precise adjustment of the assembly. Therefore, if the necessary tools and equipment especially designed for this work are not available to do a first rate job, the work should be farmed out to a Volkswagen service station or other establishment who has the facilities to do the work properly.

Rear Suspension & Brake Section

Fig. 1 Rear suspension disassembled on models except Automatic Stickshift

REAR SUSPENSION

The rear wheels are independently sprung. The inner ends of the two torsion bars are anchored in the frame cross member by a splined tube which is welded in position. The outer ends of the torsion bars, which are also provided with splines, carry the spring plates (radius arms) the hubs of which are rubber cushioned.

On all models except those equipped with the Automatic Stickshift transaxle, the rear axle tubes are attached to the rear ends of the spring plates, Fig. 1. Models using the Automatic Stickshift carry basically the same rear suspension but are equipped with new type rear axle shafts, Fig. 1a. These are of the double constant velocity type and are described in the *Automatic Stickshift section.*

The suspension is adjustable by means of splines. Screwed to the spring plate and axle shaft bearing housing is a rubber bumper which becomes active in the upper deflection range. Double-acting telescopic shock absorbers prevent excessive rebound.

Torsion Bar, Replace

1. Raise car front and rear and support in a horizontal position.
2. Remove rear wheel.
3. Disconnect cables at hand brake lever and pull them slightly towards the rear. Remove hand brake lever.
4. With a chisel, mark position of spring plate in relation to rear axle bearing housing. Mark on spring plate must be dead in line with groove in bearing housing.
5. Remove shock absorber lower mounting bolts.
6. Except Automatic Stickshift models, remove bolts at axle shaft bearing housing. Pull rear axle towards rear until it clears spring plate. On models equipped with the Automatic Stickshift, remove constant velocity joint bolts and remove axle.
7. Remove spring plate hub cover.
8. Remove spring plate and both rubber cushions.
9. Remove five of the foremost fender screws. Pull fender aside and remove torsion bar from frame cross tube.

NOTE: If the torsion bar is broken, push the broken end from the splined center anchor with a steel rod after having removed opposite torsion bar.

INSTALLATION

1. Inspect splined ends of torsion bar and paint for damage. If damaged or if there are signs of rust, install a new bar.
2. Grease torsion bar splines. Install bar and spring plate.

IMPORTANT: Torsion bars are prestressed. Left and right bars are not interchangeable and are identified by an arrow on the outside face showing the direction of torque.

Fig. 1a 1968-69 double jointed axle

3. Apply graphite on rubber cushions when installing them.
4. Lift spring plate with the aid of Spring Plate Tensioner VW655 until its lower edge is higher than the lower stop in cross tube flange. Then press spring plate in position with Spring Plate Installing Tool VW-656.
5. Install and tighten spring plate hub cover.

NOTE: To facilitate installation of hub cover and to avoid damage to threads, screw two tapered guide pins (about 1.8″ long) in two diagonally opposite tapped holes. The cover is then pushed over the guide pins, allowing two of the cover bolts to be installed. Then remove the guide pins and install remaining screws.

6. Clean mating surfaces between spring plate and axle bearing housing.

NOTE: When bolting spring plate and axle bearing housing together, make sure that the mark made on spring plate previously is dead in line with the groove in the axle bearing housing. Tighten bearing housing bolts to 72-87 ft-lbs.

7. Install hand brake lever and adjust hand brake.

Spring Plate, Adjust

It is very important that there be no difference in the inclinations of both spring plates if perfect riding qualities under all conditions of load are to be insured. When adjusting one spring plate

Fig. 2 Lifting spring plate with Torsion Bar Tensioner VW655

Fig. 3 Protractor VW245a mounted on spring plate

Fig. 6 Adjust wheel brake

Fig. 4 Drum type front brake

Fig. 5 Rear wheel brake

the inclination of the other should be checked and adjusted if necessary.

An exact adjustment of the rear suspension is effected by measuring the inclination of the spring plate with the frame in the horizontal position and with spring plate unloaded. The inclination of the unloaded spring plate should be as shown in table below. The adjustment is made as follows:

1. Check horizontal position of vehicle by placing a protractor (VW245a) on door opening.
2. Insert inner end of torsion bar in center anchor.
3. Press spring plate on outer end of torsion bar, Fig. 2.
4. Place protractor on the unloaded spring plate, Fig. 3. To obtain a correct reading the half axle must be supported.
5. Adjust protractor until bubble is in center position.

NOTE: If the protractor indicates a departure from the prescribed inclination the adjustment is to be corrected. There are more splines on the outer end of the torsion bar than at the inner end, so an exact adjustment is possible.

6. If the inner end of the bar is turned by one spline the adjustment is altered by 9°. If the spring plate is displaced by one spline the adjustment is altered by 8°10′. Thus the inclination of the spring plate can be corrected by 0°50′.

Spring Plate Adjustment

Car Model	Spring Plate Angle①
1200	16½°
1200A, 1300	17½°
1967-68 1500 Except Auto. Stickshift	17½°
1968 1500 Auto. Stickshift	21½°
1965-66 1500 Sedan, Coupe	20½°
1965-66 1500 Variant	18½°
1965-66 1500 Variant Deluxe	21½°
1600 Fastback	20½°
1600 Squareback	21½°

①—Plus or minus 5/6 deg.

Fig. 7 Disc brake assembly

Fig. 8 Pushing pistons into their end positions with special pliers

Rear Wheel Alignment

The holes provided in the spring plate for attaching it to the axle bearing housing are elongated. A groove is provided on the side of the spring plate and on the axle bearing housing above the top mounting hole. When adjusting the wheels without an alignment gauge these two grooves must be dead in line.

The camber angle of the rear wheels with the vehicle unloaded and correct spring plate adjustment is 3° (plus or minus 30′). Small deviations on both wheels do not influence road-holding ability. However, it is important that the wheels have the same camber angle, the maximum deviation being 20′. Incorrect camber readings are to be corrected as follows:

1. If camber angle is too wide but equal on both wheels, re-adjust spring plates.
2. If camber angle is too narrow but equal on both wheels, it indicates that spring plates have settled and should be re-adjusted.
3. If camber angle is uneven on both wheels, the spring plates may be unevenly adjusted, in which case they require re-adjustment. Another cause would be if the rubber cushions are improperly seated in the spring plates, in which case apply graphite to the cushions.

BRAKES

The brake shoes are self-centering and rest freely in the slots of the wheel cylinder piston push rods and adjusting screws. The hold-down springs, Figs. 4 and 5, assure a constant contact of the shoes with the bosses on the brake backing plate. The brake shoes are adjusted by means of screws and nuts at the anchor block.

Wheel Brakes, Adjust

1. Raise car and release hand brake.
2. Depress brake pedal several times to centralize the shoes in the drums.
3. Turn the wheel forward until the hole in the brake drum is in line with one of the adjusting nuts.
4. Insert a screwdriver through this hole, Fig. 6. and turn the adjusting nut, using the screwdriver as a lever until a slight drag is noted when wheel is turned by hand.
5. Back off adjusting nut 3 to 4 teeth to allow the wheel to turn freely.

NOTE: Repeat the procedure on the other adjusting nut, noting the opposite turning direction of the two nuts.

6. Repeat on the other wheels.

Hand Brake, Adjust

1. Raise rear of car.
2. Fold back hand brake lever rubber boot until brake cable adjusting nuts are accessible.
3. Back off lock nuts and tighten adjusting nuts to the point which will still allow the rear wheels to turn freely when hand brake lever is in released position.
4. Pull hand brake lever up two notches, and make sure both rear wheels have the same braking effect. At the fourth notch, the rear wheels should lock.
5. Tighten lock nuts and fasten rubber boot.

Master Cylinder, Replace

1. Pull rubber plug off master cylinder and allow fluid to drain into a clean container if it is still usable.
2. Disconnect stop light cable.
3. Disconnect brake line and plug opening.
4. Remove piston push rod-to-brake pedal bolt and loosen pedal stop.
5. Remove piston push rod.
6. Unfasten master cylinder (2 nuts) and withdraw master cylinder toward front.
7. Disconnect line between brake fluid reservoir and master cylinder. Unscrew bolt from base of reservoir and remove reservoir.
8. When installing, adjust piston push rod to 2.05″ to 2.09″ measured from convex end to face of nut. Adjust brake pedal free play by shifting stop plate until clearance is 0.04″ between push rod and piston.

DISC BRAKES

The front brakes are of the disc type, Fig. 7, the main parts being the brake disc and caliper which contains the hydraulically operated components of the brake system. A splash shield, attached to the steering knuckle, protects the brake disc inner surface from dirt, stone damage or similar damage. The outer side of the brake disc is protected from damage by the wheel.

Friction Pads

The friction pads must be checked for wear every 6000 miles. Pads that have worn down to a thickness of 5/64″ must

Fig. 9 Positioning piston with rotating pliers

Fig. 10 Checking piston position with piston setting gauge

be replaced with new ones.

IMPORTANT: All four friction pads must always be renewed together. It is not permissible to renew single friction pads or both pads of only one wheel. In addition, the spreader springs of both calipers must also be renewed with the friction pads. All necessary parts are furnished in a repair kit.

Removal

1. Remove front wheel.
2. Using a punch, drive out pad upper retaining pin.
3. Remove pad spreader spring.
4. Using a punch, drive out pad lower retaining pin.
5. Pull pads out of caliper, using a suitable hook.

IMPORTANT: If the friction pads are to be reused, they and the appropriate caliper housings must be marked as it is not permissible to change the pads from the outside to the inside and vice versa or from the right to the left wheel.

Installation

1. Oily friction pads and those with deep cracks or which have become detached from the metal plate must be renewed. In this case, all four friction pads must be renewed.
2. If pads are to be reused, remove excess dirt from grooves.
3. Push both pistons into their end positions with the retaining pliers shown in Fig. 8.

IMPORTANT: When doing this, the brake fluid behind the piston in the cylinder is forced back into the fluid reservoir. To prevent the reservoir overflowing, some of the fluid must be removed from the reservoir with a container that is used only for brake fluid. Brake fluid is poisonous and must not be siphoned off with a hose.

4. Clean seating and sliding surfaces of friction pads in brake caliper. To do this, remove piston retaining plates. Never used petroleum products for cleaning. After cleaning, blow out with compressed air.
5. Check rubber boot for damage. Hardened, brittle or cracked boots must be replaced. To replace a rubber boot the brake caliper must be removed.
6. Insert piston retaining plate. The circular part of the plate must be firmly pressed into the piston crown. In addition, the plate must lie below the relieved part of the piston. When the retaining plate is correctly installed, the 20° position of the piston is correct. Corroded or damaged piston retaining plates must be replaced.
7. Correct position of piston, if necessary, with piston rotating pliers, Fig. 9.
8. Check position of piston again, using a piston setting gauge, Fig. 10. The gauge must be held against the lower guide surface in the brake caliper which is counterclockwise to the brake disc rotation (arrow) when driving the vehicle forward.
9. Check brake disc for wear.
10. Insert pads into brake caliper. The pads must be free enough to move to and fro in caliper.
11. Insert pad lower retaining pin into caliper.

IMPORTANT: The retaining pin must not be driven in with a punch smaller in diameter than the pin as the front shoulder can easily be sheared off by the split clamping bushing. It is advisable to drive in the retaining pins with a hammer only and no additional tools.

12. Install new pad spreader spring.
13. Push in pad upper retaining pin after first pressing spreader spring down with thumb.

IMPORTANT: Depress brake pedal several times while vehicle is stationary to enable pistons and pads to assume their correct positions to the brake disc.

Front Axle & Steering Gear Section

FRONT AXLE

Series 1200 to July 1965

Referring to Fig. 1, the supporting part of the front axle is the axle beam which consists of two rigidly joined tubes fixed to the frame head with four screws. Inside the tubes are the torsion bars which are made up of eight spring leaves each and are anchored in the middle to prevent twisting and lateral movement. The torsion arms which are fitted on the ends of the torsion bars are mounted in the tubes in a plastic bushing and needle bearing on each side. The torsion arm links and steering knuckles are attached to the torsion arms by adjustable pins and are free to pivot. A steering knuckle (stub axle) swivels on a kingpin which passes through bushings in the link. A thrust bearing is located between the upper end of the steering knuckle and the link.

1200, 1300 From August 1965 & 1967-68 1500

As shown in Fig. 2, this front axle is similar to that shown in Fig. 1. However, the torsion bars consist of ten spring leaves instead of the eight leaves used formerly. Ball joints are used instead of the former kingpins. The ball joints connect the torsion arms to the steering knuckles. They are pressed into the torsion arms and bolted to the steering knuckles. The upper ball joints engage in eccentric bushings with which front wheel camber can be adjusted.

1965-66 1500; All 1600

As shown in Fig. 3, the front axle is a complete replaceable assembly that can be detached from the frame fork quickly. The axle is mounted on the frame in rubber collars which prevent the transmission of road noises to the body. The wheels are independently suspended so that shocks taken on one wheel are not transferred across the vehicle to the opposite wheel.

The axle beam is of fabricated sheet steel construction that must be replaced as a unit when damaged. It is made up of two shells welded together. Side plates welded on each end reinforce the axle beam and also carry the upper mounting points for the shock absorbers. Bearing tubes are welded inside the axle beam to locate the torsion arms.

The torsion arms are supported in needle bearings at the outer points and plain metal bushings at the inner points. These needle bearings and bushings are replaceable.

Torsion Bars

Springing of the front wheels is provided by a separate, adjustable torsion bar for each wheel. The torsion bars are made of round material with upset ends that are splined. An internally splined bushing is welded into each side plate and the splined ends of the torsion bars are inserted into these bushings and secured with a screw on each side.

Stabilizer

The upper torsion arms are connected by a stabilizer bar that is fitted to improve road holding. The stabilizer bar has square upset ends that fit into the upper torsion arms. The left upper torsion arm is secured by means of an integral hexagon socket setscrew that engages in a countersunk depression in the stabilizer and is locked with a locknut. The right upper torsion arm is secured with an adjusting screw and a clamp screw. The adjusting screw is used to set the torsion arm axial movement.

Ball Joints

The pins in the ball joints have square ends at the bottom so that the pins can be turned to adjust wheel camber.

WHEEL ALIGNMENT

Caster Angle

If the caster angle does not conform to the specifications listed in the *Wheel Alignment Specifications* table, examine for distortion in the axle tubes or beam or frame head to which the axle is attached. Otherwise caster is not adjustable.

Fig. 1 Front axle assembly with kingpins. Series 1200 to July 1965

Fig. 2 Front axle assembly with ball joints. Series 1200, 1300 from August 1965 & 1967-68 1500

Fig. 3 Front axle assembly. 1965-66 1500 & All 1600

Camber Angle

1200, 1300 From August 1965 & 1967-68 1500

The camber angle cannot be adjusted on vehicles manufactured up to August 1965. Deviations from the prescribed specifications can, therefore, only be caused by wear or distortion of front axle parts. It is not permissible to correct camber by altering the prescribed positions of the washers.

On vehicles manufactured from August 1965, camber angle can be adjusted by an eccentric bushing on the upper ball joint. To do this, loosen the hexagon nut on upper ball joint and turn eccentric bushing as required to obtain the proper camber angle as listed in the *Wheel Alignment Specifications* table.

IMPORTANT: The eccentric bushing is provided with a notch which, in the basic position, must face in the normal driving direction. This notch may be moved a maximum of 90° to the left and right of this basic position.

1965-66 1500; All 1600

The pins in the ball joints have square ends so they can be turned to adjust camber as required. Only the upper ball joints are to be adjusted. This will prevent the wheel steering lock angles from being enlarged.

The ball joints are marked with a notch on the pin end which shows the position of the eccentric. In the basic position, the mark points to the front. The eccentric may only be turned a maximum of 90° to right and left from this position.

Wheel Toe-In

1. First make sure that there is no front wheel run-out, and that the wheel bearings, torsion arm link pins and tie rod ends are not excessively worn.
2. Turn wheels exactly to their straight-ahead position.
3. Force the front wheels apart at the front to take up any slack in the wheel suspension and tie rods.
4. Check the toe-in in the conventional manner. If toe-in does not conform to the specifications called for in the Wheel Alignment chart, adjust as follows:
5. Loosen lock nut at both ends of the adjustable tie rod. Adjust toe-in by turning the tie rod until correct toe-in is obtained and tighten lock nuts.

WHEEL BEARINGS, ADJUST

1965-66 1500; All 1600

1. Lift front of vehicle.
2. Check that brake drums or discs turn freely. Brake linings must not rub.
3. Pull hub caps off.
4. Remove one wheel bolt and mount a dial gauge in the threaded bolt hole.
5. Set dial gauge so that feeler pin is touching outer hexagon nut or clamp nut.
6. Move wheel in and out firmly. End play should be from .001″ to .005″. If not within this range, adjust as follows:

NOTE: When play is at the upper limit, the wheel has quite a noticeable amount of rock. This is in order and there is no need to re-adjust the bearings. A re-adjustment is necessary only if isolated complaints of front axle noises are received. In such a case, try to adjust the bearings to obtain as near to the low limit as possible (.0012″ to .0024″).

7. Tighten inner nut or clamp nut to not more than 11 ft-lbs. Wheel must be turned while doing this so that bearing rollers contact shoulder of inner bearing race.
8. Slacken off the adjustment until play is between .0012″ and .0048″ when wheel is moved firmly in and out.
9. On drum brakes, hold inner bearing nut and tighten lock nut to 50 ft-lbs.
10. On disc brakes, tighten clamp nut screw to 7 ft-lbs.
11. Check adjustment again and if satisfactory, secure lock nuts or clamp screw nut.

Series 1200, 1300 from August 1965 & 1967-68 1500

1. Bend tab of lock plate on spindle and use two wrenches to loosen both nuts. Take off outer nut, discard lock

Fig. 4 Series 1200 to July 1965 front axle. NOTE: The kingpins are a press fit in the steering knuckles. Before pressing kingpins out or pressing new ones in, the knuckle must be heated in an oil bath to about 175° F.

plate and install the nut with a new lock plate, Fig. 4.

2. Tighten inner nut until thrust washer at outer bearing can just be moved laterally with a screwdriver. This is the correct adjustment provided there is no bearing end play when checked by rocking the brake drum back and forth.
3. If the foregoing conditions are met, hold the inner nut with a wrench and tighten the outer nut against the lock plate.
4. Secure the adjustment by bending the lock plate tab against nut.

TORSION ARM LINKS

Series 1200 to July 1965

Link Pins, Adjust

The link pin adjustment must be checked at regular intervals. If the adjustment is too tight, the suspension will not have the desired freedom of movement. On the other hand the link pins must not be too loose but should be adjusted so that there is no perceptible play.

1. Raise vehicle and rock wheel by hand to check for play between torsion arm links and torsion arms. If any play is indicated, adjust as follows:
2. With vehicle raised and axle free of load, lubricate link pins and kingpins.
3. Loosen pinch bolts at torsion arm eyes, Fig. 5. Pull link pins up tight, then slacken off ⅛ of a turn.
4. Tighten the pin again until the first slight resistance is felt. If the

Fig. 5 Adjusting torsion arm link pins. Series 1200 to July 1965

Fig. 6 Offset of eye face as measured with scale should be .28" (plus or minus .08")

Fig. 7 Torsion arm link pin shim installation

Fig. 8 Checking ball joint for wear with feeler gauge

Fig. 9 Notch in ball joint must line up with notch in torsion arm eye

Fig. 10 Protractor (VW 261) positioned on face of anchor plate

range of adjustment is inadequate, the shims are worn and must be replaced.

5. Every time the link pins are adjusted, the toe-in must be checked and adjusted if necessary.

Installation of Shims

1. When assembling torsion arms, first measure offset of eye faces, Fig. 6, which should be .28″ (plus or minus .08″). The offset is corrected with shims .02″ thick. Installation of retainer reduces number of shims from 10 to 8.
2. There must always be 8 shims and one retainer with dust excluder fitted to one torsion arm link pin ("A", Fig. 7).
3. If offset measures .2756″ "B" and "D", Fig. 7 should have 5 shims each and "A" and "C" 3 shims each.
4. If offset is in excess of .2756″, shims should be added at "A" and removed from "C".
5. If offset is below .2756″, shims should be removed from "A" and added to "C".
6. Number of shims at "B" and "D" should always be brought up to 8.

TORSION ARMS & BALL JOINTS

1200, 1300 From August 1965 & 1967-68 1500

Torsion Arm Removal

1. Remove steering knuckle complete with brake drum.
2. If lower torsion arm is to be removed, take stabilizer off.
3. Loosen lock nuts on torsion arm pins and screw pins out.
4. Pull torsion arms out of axle tubes.
5. If necessary, take sealing rings out of axle tubes.
6. Clean torsion arms and ball joints.
7. Checking bearing seats on torsion arms for wear.

IMPORTANT: Bent torsion arms or arms with worn bearing surfaces should be replaced complete with ball joints.

8. Seal ball joints with new plastic plugs.

Checking Ball Joints

1. The dust seals must be taken off to check ball joints. It is essential to ensure that no dirt gets into the joints when doing this.
2. To check upper ball joint, press out eccentric bushing.
3. Check dust seals for damage.

NOTE: If the dust seal is damaged and there is a risk of dirt having got into the ball joint, the joint must be cleaned thoroughly with a suitable solution. The plastic plug should then be removed, a grease nipple screwed in and lithium grease forced into the joint until all traces of dirt have been removed.

4. Check ball joint with feeler gauge as shown in Fig. 8. Permissable play on new joint should be .02″ with a wear limit of .08″.
5. If ball joints are in order, install dust seals and grease joint as follows:
6. According to the type of joint, secure dust seal to housing with a .04″ diameter wire or with spring ring.
7. Fit dust seal plastic clip on pin end of joint, using a suitable sleeve to aid in the installation. See that the ring does not twist.
8. Lubricate joint with lithium grease by forcing grease into nipple until seal just begins to expand. This point can be detected easily if the seal is squeezed lightly with two fingers. Grease nipple is then screwed out and a new plug is installed.

Fig. 11 Mandrel inserted in torsion arm

Fig. 12 Protractor swiveled against shock absorber mounting bolt

Fig. 13 Tightening torsion arm set screw

Replacing Ball Joints

1. Press upper ball joint out of torsion arm. If necessary, press eccentric

Fig. 14 Steering gear assembly

Fig. 15 Steering gear points of adjustment

bushing off ball joint. Press in new ball joint, being sure that notch in joint is in line with notch in torsion arm eye, Fig. 9.

IMPORTANT: For production reasons, ball joints with a .16″ oversize knurl are occasionally installed in the torsion arms in addition to standard size ball joints. These joints are marked for installation purposes with two grooves at 180° to each other, while the standard joints have only one such groove. Pay attention to these markings when replacing ball joints as the joints have no markings indicating their sizes.

2. To replace lower ball joints, proceed in a similar manner as for upper joints. If the ball comes out of the socket when pressing the ball joint out, the socket can be pressed out of the torsion arm.

NOTE: Old ball joints must not be pressed back in again under any circumstances.

TORSION ARMS & BARS

1965-66 1500; All 1600

IMPORTANT: Removal and installation of torsion arms and bars should not be attempted without the aid of a special protractor (VW 261) and special mandrel, Fig. 10. The protractor has two spirit levels and, unless it is used to set up the proper angle of 39°10′ of the torsion arm, road holding ability of the vehicle during subsequent operation will not be achieved. However, if this equipment is available, proceed as follows:

1. Slide torsion arm onto torsion bar splines and adjust with protractor to 39°10′ + 50′ as follows:
2. Position protractor on face of anchor plate, Fig. 10. Protractor must contact at bearing surface for the upper torsion arm and level with welded-in bushing (support bearing for torsion bar).
3. Turn spirit level until bubble marked "Achskorper" is exactly in central position.
4. Remove protractor at this setting and insert mandrel in torsion arm, Fig. 11. Do not slide torsion arm fully onto torsion bar because mandrel must also be pushed into torsion arm splines.
5. Swivel protractor from underneath against shock absorber mounting bolt so that it is positioned as close as possible to torsion arm at mounting bolt, Fig. 12.
6. The torsion arm is correctly adjusted when the bubble of the spirit level marked "Traghebel" is exactly in the central position.

NOTE: The different number of splines on the torsion bar ends make it possible to correct the adjustment. There are 29 inner splines and 31 outer splines. The minimum adjustment range of 50′ is achieved by turning the torsion arm by one tooth and the torsion bar also by one tooth but in the opposite direction.

IMPORTANT: It is of the utmost importance for road holding that the adjustment angles of the lower torsion arms correspond as far as possible and are not below the prescribed angle of 39°10′. When adjusting one side, the adjustment angle of the other side must also be checked. If it is not within the tolerance range of 39°10′ + 50′, it must be corrected.

7. Install and tighten torsion arm bolt and torque to 29 ft-lbs.
8. Tighten set screw in lower torsion arm to 22 ft-lbs and secure with lock nut, Fig. 13. *This operation must be performed carefully to avoid damage to torsion bars.*
9. Install steering knuckle with brake drum, bleed brakes and adjust camber and toe-in.

STEERING GEAR

Steering Wheel

Removal

1. Disconnect battery ground cable.
2. Remove horn lever cover with screwdriver.
3. Disconnect horn ground wire at horn lever.
4. Remove steering wheel nut.
5. On 1200, 1300 & 1967-68 1500, remove spring washer. Then remove wheel with horn lever.
6. On 1965-66 1500 & all 1600, remove nut, spring washer, steering wheel and horn lever.

Installation

1. On 1200, 1300 and 1967-68 1500, position brass washer with cut-away part exactly to the right when wheels are straight ahead.
2. On 1965-66 1500 and all 1600, install

support ring and brass washer. Milled end of support ring must be toward steering gear and cut-away part of brass washer must be to the right when wheels are in straight ahead position.

3. Locate steering gear in center position and install wheel so that spokes are horizontal. Tongue of cancelling ring must engage recess in brass washer.
4. On 1200, 1300 and 1967-68 1500, install spring washer and nut and tighten to 36 ft-lbs.

NOTE: The distance between turn signal switch and steering wheel hub should be .08″ to .10″. Distance can be set by moving column on upper coupling flange as required. Connect horn cable to horn lever.

5. On 1965-66 1500 and all 1600, install spring washer and tighten nut to 36 ft-lbs. Connect horn wire to horn lever.

NOTE: The distance between turn signal switch and wheel hub should be .08″ to .12″. When the two switch screws are loosened, the column tube and switch can be moved as the holes in the housing are elongated. *The switch must only be moved when in the position to avoid damaging cancelling cams.* If the range of adjustment is inadequate, the steering column must be moved axially in the upper coupling flange.

Steering Gear, Replace

1200, 1300 & 1967-68 1500

1. Raise car and remove left front wheel.
2. Detach tie rods from steering drop arm with a suitable puller.
3. Unscrew nut on column clamp.
4. Disconnect cable on coupling contact.
5. Pull column off column flange.
6. Remove steering gear clamp.
7. Remove steering gear.
8. Reverse procedure to install.

1965-66 1500; All 1600

1. Raise vehicle and remove fuel tank.
2. Remove spare wheel well.
3. Remove both tie rods from drop arm, using a suitable puller.
4. Remove steering damper from drop arm.
5. Remove coupling bolts.
6. Disconnect ground cable.
7. Remove mounting clamp.
8. Take steering gear off axle.
9. Reverse procedure to install.

Steering Gear, Adjust

Gear Installed In Car

1. With wheels on floor and facing straight ahead, move steering wheel lightly to and fro until resistance is felt in both directions. This range at the center position is determined by the steering adjustment as well as by the tie rods and steering coupling. Measured at the steering wheel rim the free play should be 1 inch.
2. If there is excessive play in the center position, there are three adjustments that can be made: axial play of steering worm, play between worm and roller, and axial play of steering roller, Fig. 15.

Axial Play of Worm

The axial play of the worm is determined by turning the worm to and fro at the steering coupling. To do this, the vehicle must be raised. If there is play, it can be eliminated as follows:

1. Turn steering wheel fully to left or right.
2. Loosen locknut on steering worm adjusting screw, Fig. 15.
3. Turn worm to and fro at coupling and at the same time tighten worm adjusting screw until play is no longer detectable.
4. Hold adjusting screw and tighten locknut.
5. Turn steering worm from one extreme to the other. When turning, there should be no unusually tight positions noticeable. If there are any, the adjusting screw is too tight, and must be corrected.

Play Between Worm and Roller

If play in the steering cannot be eliminated by adjusting the worm, the roller-to-worm setting must be adjusted. There should be no play between roller and worm with steering in central position. The worm-to-roller adjustment can be made with the vehicle raised. However, to make the adjustment the vehicle must be on the ground.

1. Turn steering wheel 90° left or right.
2. Loosen roller shaft adjusting screw locknut.
3. Loosen adjusting screw about one turn.
4. Tighten adjusting screw until roller can be felt contacting worm.
5. Hold adjusting screw and tighten locknut 14 to 18 ft-lbs.
6. Check the adjustment with steering wheel turned 90° to each side with vehicle resting on ground. The play must not exceed 1 inch, measured at the rim of the steering wheel. If there is more play on one side, the adjustment of the roller to the worm at the 90° position should be repeated on this side.
7. Check toe-in and adjust if necessary.
8. Road test. If steering does not return to within 45° of the central position after making a turn at 10 to 12 mph, the roller is too tight. The adjustment should then be repeated, otherwise the worm and roller will be damaged.

Roller Axial Play

If the steering gear cannot be properly adjusted by the foregoing adjustments, the gear must be dismantled and axial play of the roller checked.

1. With steering gear disassembled, the axial play of the roller should not exceed .0016″.
2. Measure play between roller and washer with a .002″ feeler gauge. If feeler gauge can be inserted between roller and washer, the roller shaft should be replaced.
3. Assemble, adjust and install steering gear. Check and adjust toe-in if necessary, and road test vehicle.

①—Before Engine No. LAA-283230 and LAQ-117209, set timing 7/32″ after timing ball. Starting with these engine numbers, set timing at the ball.
②—Turn rocker arm adjusting screw down until all lash is removed. Then turn screw down the additional number of turns specified.
③—New points .019″, used points .016″.
④—Cylinder numbering (front to rear): Left bank 1-3-5-7, right bank 2-4-6-8.
⑤—New Points .018″, used .015″.
⑥—Each set of points 28–30° total both sets 33–35°.
⑦—For long travel lifters 2 turns.
⑧—First short vertical line clockwise from ball in flywheel.

①—There are no timing marks. Spark can be advanced or retarded by adjusting the vacuum brake set screw on distributor housing.

②—Total dwell for both breakers.

③—Cylinder numbering (front to rear): Right bank 1-2-3-4, left bank 5-6-7-8.

④—Up to Serial No. 8BA-622468: intake .012C, exhaust .014C. Later cars, intake .014C, exhaust .018C.

⑤—Clearance specified is obtainable at valve stem tip with lifter collapsed.

SPARK PLUG CONDITION CHART

CARBON FOULED

IDENTIFIED BY BLACK, DRY FLUFFY CARBON DEPOSITS ON INSULATOR TIPS, EXPOSED SHELL SURFACES AND ELECTRODES.
CAUSED BY TOO COLD A PLUG, WEAK IGNITION, DIRTY AIR CLEANER, DEFECTIVE FUEL PUMP, TOO RICH A FUEL MIXTURE, IMPROPERLY OPERATING HEAT RISER OR EXCESSIVE IDLING.
CAN BE CLEANED.

OIL FOULED

IDENTIFIED BY WET BLACK DEPOSITS ON THE INSULATOR SHELL BORE ELECTRODES CAUSED BY EXCESSIVE OIL ENTERING COMBUSTION CHAMBER THROUGH WORN RINGS AND PISTONS, EXCESSIVE CLEARANCE BETWEEN VALVE GUIDES AND STEMS, OR WORN OR LOOSE BEARINGS. CAN BE CLEANED IF ENGINE IS NOT REPAIRED, USE A HOTTER PLUG.

GAP BRIDGED

IDENTIFIED BY DEPOSIT BUILD-UP CLOSING GAP BETWEEN ELECTRODES.
CAUSED BY OIL OR CARBON FOULING. IF DEPOSITS ARE NOT EXCESSIVE, THE PLUG CAN BE CLEANED.

LEAD FOULED

IDENTIFIED BY DARK GRAY, BLACK YELLOW OR TAN DEPOSITS OR A FUSED GLAZED COATING ON THE INSULATOR TIP
CAUSED BY HIGHLY LEADED GASOLINE. CAN BE CLEANED.

NORMAL

IDENTIFIED BY LIGHT TAN OR GRAY DEPOSITS ON THE FIRING TIP
CAN BE CLEANED.

WORN

IDENTIFIED BY SEVERELY ERODED OR WORN ELECTRODES.
CAUSED BY NORMAL WEAR.
SHOULD BE REPLACED.

FUSED SPOT DEPOSIT

IDENTIFIED BY MELTED OR SPOTTY DEPOSITS RESEMBLING BUBBLES OR BLISTERS.
CAUSED BY SUDDEN ACCELERATION. CAN BE CLEANED.

OVERHEATING

IDENTIFIED BY A WHITE OR LIGHT GRAY INSULATOR WITH SMALL BLACK OR GRAY BROWN SPOTS AND WITH BLUISH-BURNT APPEARANCE OF ELECTRODES, CAUSED BY ENGINE OVERHEATING. WRONG TYPE OF FUEL, LOOSE SPARK PLUGS, TOO HOT A PLUG, LOW FUEL PUMP PRESSURE OR INCORRECT IGNITION TIMING. REPLACE THE PLUG.

PRE-IGNITION

IDENTIFIED BY MELTED ELECTRODES AND POSSIBLY BLISTERED INSULATOR. METALLIC DEPOSITS ON INSULATOR INDICATE ENGINE DAMAGE.
CAUSED BY WRONG TYPE OF FUEL, INCORRECT IGNITION TIMING OR ADVANCE, TOO HOT A PLUG, BURNT VALVES OR ENGINE OVERHEATING.
REPLACE THE PLUG.

Fig. 1 Rotor type power steering pump disassembled (typical)

Fig. 2

Fig. 3

Fig. 4

Fig. 5

Pump Section

ROTOR TYPE PUMP

This unit, Fig. 1, consists of the reservoir, pressure relief valve, filter element, and the rotating pump gearing. The pump reservoir illustrated has a filler cap with a fluid level checking gauge.

Disassembly

1. Remove reservoir filler cap.
2. Loosen reservoir mounting bolt and remove cover.
3. Remove filter element.
4. Drain oil from reservoir.
5. Remove return stud from body, Fig. 2.
6. Remove reservoir-to-body mounting screws.
7. Remove reinforcement plate and reservoir.
8. Remove four O-ring seals, Fig. 3.
9. Remove intake O-ring seal retainer.
10. Remove cover-to-body mounting screws and separate body from cover, Figs. 4 and 5.
11. Remove gasket, and O-ring seal from body, Fig. 5
12. Scribe a line on inner and outer rotors for reassembly purposes, Fig. 6.
13. Remove outer and inner rotors.
14. Remove inner rotor drive pin from shaft.
15. Remove bearing retaining ring with snap ring pliers.
16. Remove shaft and bearing from body.
17. Press bearing from shaft.
18. Remove seal from body, using a suitable puller.

Fig. 6

Fig. 7

Fig. 8

Fig. 9

19. To remove the combination flow control and relief valve in the pump cover, remove the spring retainer cap fitting and circular section rubber O-ring seal and discard seal, Fig. 7.
20. Lift out flow control valve spring.
21. Tap cover on wooden block to remove combination flow control and relief valve.
22. To remove pressure relief valve and spring from flow control valve body, place valve in vise. Place punch against relief valve and remove spring pressure. Remove retaining ring, Fig. 8, using internal snap ring pliers. Then remove relief valve and spring, Fig. 9.

Reassembly

Clean all parts and air dry only. Coat all parts with a light film of oil as assembly progresses. This will assure initial lubrication of parts.

1. The relief valve spring weight should be checked with a spring tester before preassembling the flow control valve. The spring load is usually between 14 and 16 pounds when compressed to a length of $1\frac{3}{16}$".
2. Preassemble the flow control valve as shown in Figs. 8 and 9.
3. Install flow control valve in pump cover.
4. Install flow control valve spring.
5. Install new O-ring seal on flow control valve cap fitting and install into pump cover.
6. Install new seal with lip toward rotor into pump body, using a suitable seal driver.
7. Press bearing onto shaft until bearing seats against shoulder on shaft.
8. Install shaft and bearing into pump body.
9. Install bearing retaining ring.
10. Install inner rotor drive pin in shaft groove.
11. Install inner rotor, making sure scribe line is facing upward.
12. Install outer rotor, making sure scribe line is facing upward.
13. After rotors have been nested in pump body, the tooth nose clearance should be checked with a feeler gauge as shown in Fig. 10. If the clearance exceeds .008", replace rotors with a new set. Also the end clearance should be checked as shown in Fig. 11, and in the event that it exceeds .0025", the rotors must be replaced with a new set.
14. Install new O-ring seal in body.
15. Install new body-to-cover gasket.
16. Position cover on body and torque cover screws to 20-25 ft-lbs.
17. Rotate pump shaft and check for free rotation.
18. Install O-ring seal retainer into body.
19. Position four new O-ring seals on pump body to mount reservoir.
20. Position reservoir over the four O-ring seals and pump body.
21. Place reservoir reinforcing plate into position.
22. Secure reservoir and plate to body with two screws and lockwashers.
23. Install pump return stud in body.
24. Install new filter element.
25. Install new cover gasket with cover and tighten securely.

ROLLER TYPE PUMP

This type pump, Fig. 12, consists of the reservoir, pressure relief valve, filter element, and the rotating pump cam.

Thoroughly clean exterior of pump and reservoir, using care so that dirt does not enter pump or reservoir upon disassembly. During all assembly operations, extreme caution must be used to prevent any dirt from entering pump. All parts should be lightly oiled during reassembly to provide initial lubrication.

Fig. 10

Fig. 11

Disassembly

1. Remove reservoir cover, gasket, filter element spring, spring seat and filter element.
2. Remove $\frac{5}{16}$" stud with stud puller or two nuts, Fig. 13.
3. Remove stud that retains filter element support, Fig. 14.
4. Remove reinforcing plate and reservoir.
5. Remove four O-ring seals between reservoir and pump body and discard seals, Fig. 15.
6. Remove cover-to-body mounting screws and studs, Fig. 16. Separate cover from body, Fig. 17, lifting cover vertically from body to prevent internal parts from falling out.
7. Remove O-ring seals from grooves in pump housing, Fig. 17, and discard seals.
8. Before removing carrier, mark a line across the carrier and cam, Fig. 18. This will permit correct reassembly as the carrier has a drive side and must be installed as shown. Do not scratch surfaces when making marks.
9. Remove rollers, carrier and drive pin from shaft. Then lift out cam and cam retaining pin, Fig. 19.
10. Remove bearing retaining ring. Remove shaft and bearing from body, and press bearing from shaft.
11. Remove seal from body, using a suitable seal puller.

Fig. 12 Roller type power steering pump disassembled (typical)

Fig. 13

Fig. 14

Fig. 15

12. To remove combination flow control and relief valve in pump cover, Fig. 20, remove spring retainer cap and O-ring seal; discard seal.
13. Lift out flow control valve spring.
14. Tap cover on wooden block to remove combination flow control and relief valve, Fig. 21. *The relief valve is an internal part of the flow control valve and is not to be disassembled.*

Reassembly

1. Install flow control valve into pump cover, making sure exposed ball enters bore first.
2. Install flow control valve spring.
3. Install new O-ring seal on flow control valve retainer cap and install into pump cover. Torque retainer cap to 30-35 ft-lbs.
4. Install new seal with lip toward carrier into pump body, using a suitable seal driver.
5. Press bearing onto pump shaft until bearing seats against shoulder on shaft.
6. Install shaft and bearing into body.
7. Install bearing retainer ring in groove in body, making sure ring is seated properly.
8. Install cam retaining pin into body.
9. Install cam into body, making sure notch in cam indexes with retaining pin and cam is seated firmly in pocket.
10. Install carrier drive pin into groove in pump shaft.
11. Install carrier into pump body, making sure line previously marked on carrier indexes with line marked on cam.
12. Install rollers into pockets of carrier.
13. After the cam, carrier and rollers have been placed in pump body, the end clearance of carrier and rollers in body should be checked, Fig. 22. If end clearance exceeds .002", replace carrier or rollers.
14. Install new O-ring seals in body.
15. Position cover on body and torque screws and studs to 20-25 ft-lbs. Rotate pump shaft and check for free rotation.
16. Position four new O-ring seals on pump body to mount reservoir.
17. Position reservoir over four O-ring seals and body.

Fig. 16

Fig. 17

Fig. 18

Fig. 19

Fig. 23 Slipper type power steering pump

Fig. 20

Fig. 22

Fig. 21

Fig. 24 Removing pump pulley

18. Secure reservoir and reinforcing plate and torque screws to 30-35 ft-lbs.
19. Install filter element support and torque stud to 30-35 ft-lbs.
20. Install $\frac{5}{16}$" stud into support stud and torque to 40-60 inch-lbs.
21. Place new filter element on support. Position spring seat on top of filter. Install spring over stud and onto spring seat. Install reservoir cover with new gasket. Install reservoir cap.

Fig. 25 Removing pump oil seal

Fig. 26 Installing oil seal

Fig. 27 Installing pump pulley

SLIPPER TYPE PUMP

NOTE: Disassembly of the slipper type pump, Fig. 23, is not recommended as the internal parts of the pump are not serviced separately. The only parts that are serviced are the pump assembly, filler cap, reservoir, O-ring and gasket, pump shaft oil seal, flow control plug and O-ring, snap ring and relief valve.

Disassembly

1. Clean exterior of pump.
2. Remove filler cap and drain reservoir.
3. Remove brackets, reservoir screws, gaskets and O-ring.
4. Using spacer washers between front bracket and pump, reinstall front bracket for use as a holding fixture. Clamp bracket in a vise.
5. Use a suitable puller to remove pulley, Fig. 24.
6. Remove relief valve and gasket.
7. Remove flow control valve plug snap ring.
8. Remove flow control valve plug and O-ring by gripping end of plug with needle nose pliers. *Caution: The valve is spring loaded.*
9. Remove oil seal by threading a suitable tool far enough to engage metal portion of seal. Then by turning the center puller screw while holding the tool body will force the seal from the pump, Fig. 25.

Inspection

Clean parts in mineral spirits or other suitable solvent. Discard body-to-reservoir O-ring and flow control valve plug O-ring. Pump shaft should turn freely and should be smooth at seal contact area. Flow control valve bore and valve should be smooth, free of scores or scratches. Valve must operate freely in bore.

NOTE: Small scratches can be removed with crocus cloth. Do not round off the square edges on the valve as they are vitally important to this type of valve. The housing bore should not be honed. If the bore is scratched or worn, the pump should be replaced.

Reassembly

1. Install flow control valve spring and valve. Lubricate and assemble a new O-ring on the flow control valve plug and install plug.
2. Install snap ring in bore.
3. Install new oil seal with lip of seal toward pump.
4. Install pressure relief valve and gasket. Tighten plug to 30 ft-lbs. torque.
5. Remove front bracket. Support pump body on a holding fixture, Fig. 26. Pump must be supported in the manner shown when installing the seal so that all pressing force will be applied to the shaft only; otherwise the pump body and rotor will be damaged.
6. Install pulley with a heavy duty arbor press, Fig. 27. Press on pulley hub only until hub is flush with end of pump shaft.
7. Lubricate large O-ring and reservoir cap screw gasket and install both on pump body.
8. Install reservoir and pump brackets. Torque screws to 10 ft-lbs.

VANE TYPE PUMP

Disassembly

1. Referring to Fig. 28, carefully mount pump in vise with soft jaws and remove reservoir cap.

NOTE: When clamping pump in vise, do not exert excessive force on front hub as this may distort drive shaft bushing in housing.

2. Remove rear pump mounting stud and O-ring seal, pressure union and O-ring seal.
3. Remove reservoir, and second pressure union O-ring seal.
4. Using a small punch, depress end plate retaining ring enough to allow removal from groove. Use the 1/8" diameter hole in housing, Fig. 29. Then remove retaining ring with screwdriver.
5. Remove end plate which is spring-loaded and will usually sit above housing level. If end plate sticks, a slight rocking action should free it. If rocking action fails to free plate, use a magnet.
6. Remove two pressure springs from pump housing.
7. Remove flow control valve and spring by inverting housing. Do not disassemble flow control valve as it is serviced as a unit and pre-set at the factory, Fig. 30.
8. Remove drive shaft key from slot in shaft. Then with end of shaft pointed downward, press down until shaft is free.
9. Turn assembly over and remove drive shaft and rotary group.
10. Remove rotor retaining ring from groove in drive shaft. Remove rotor and thrust plate from shaft, Fig. 28.
11. Remove and discard O-ring seals from pump housing. Remove drive shaft oil seal only if inspection shows necessity for replacement.

Inspection

1. Clean all parts except the drive shaft oil seal in cleaning fluid. The seal will be damaged if immersed in cleaning fluid.
2. Check fit of vanes in slots of rotor for tightness or excessive looseness. Vanes must fit snugly but slide freely in slots in rotor. Tight fit of vanes in rotor can usually be corrected by thorough cleaning. Replace rotor if excessive looseness exists between rotor and vanes. Replace vanes if worn or scored.
3. Examine machined surface of pump ring for roughness or wear. Replace ring if roughness cannot be corrected with crocus cloth.
4. Inspect thrust plate, pressure plate and end plate for wear, scores or other damage.
5. Inspect pump housing for cracks or damage. Check housing for evidence of wear or scoring.
6. Check all springs for free length, distortion or collapsed coils.
7. Inspect locating dowel pins for distortion.
8. Examine outer diameter of flow control valve for scoring or roughness. Slight damage may be cleaned up with crocus cloth. Check valve assembly for freedom of movement

Fig. 28 Vane type power steering pump disassembled (typical)

Fig. 32 Installing drive shaft assembly

Fig. 33 Installing pump ring

Fig. 29 Removing end plate retaining ring

Fig. 30 Removing flow control valve and spring

Fig. 34 Installing rotor vanes

in bore of pump housing.

9. Check all oil passages in pump parts for obstruction. Use a piece of tag wire to clean out holes.
10. Check bushing in pump housing for wear or damage.

Reassembly

1. Lubricate new O-ring seals with vaseline and place in pump housing.
2. If drive shaft oil seal was removed during disassembly, lubricate new seal with vaseline. Then install seal in pump body front hub, using a suitable seal driver.
3. Position thrust plate and rotor on drive shaft. Then install rotor retaining ring in groove of drive shaft.
4. Place pump housing on work bench as shown in Fig. 32 and install two pump ring dowel pins in bore of housing.
5. Install drive shaft assembly in housing, making sure shaft seats properly.
6. Install pump ring in housing over two dowel pins with rotation arrow on ring to rear of pump housing, Fig. 33.

NOTE: Arrow on outer edge of pump ring points in direction of pump rotation (counterclockwise when viewed from rear of pump).

7. Install rotor vanes in slots of pump rotor, with radius edge of vanes toward outside of rotor, Fig. 34.
8. Position pump housing on two wood blocks and push parts down into place as shown in Fig. 35.
9. Lubricate outside diameter and chamfer of pressure plate with vaseline to insure against damage to O-ring seals in housing. Then install pressure plate in housing over dowel pins.

NOTE: Ported face of pressure plate goes toward pump ring, Fig. 35.

10. Using a 2¾" diameter sleeve to apply pressure to outer edge of pressure plate only, press pressure plate in to seat.

NOTE. Pressure plate will travel about $\frac{1}{16}$" to seat. Do not press or hammer on center of pressure plate as to do so will cause permanent distortion resulting in pump failure.

11. Install two pressure plate springs, one over each dowel pin in pump housing, Fig. 36.
12. Lubricate outside diameter and

Fig. 35 Installing pressure plate

Fig. 36 Installing pressure plate springs

Fig. 38 Installing flow control valve and spring

Fig. 37 Installing end plate and retaining ring

Fig. 39 Installing pressure union O-ring seal

chamfer of end plate with vaseline to insure against damage to O-ring seal in housing. Then press end plate into housing. While holding end plate down in housing, install end plate retaining ring. Be sure end plate is completely and solidly seated in groove of housing, Fig. 37.

13. Remove assembly from press and place on work bench. Install flow control spring and valve in bore of housing. Make sure hex head screw of valve goes into bore of housing, Fig. 38.
14. Position pressure union O-ring seal in bore of housing over flow control valve, Fig. 39.
15. Mount pump housing in vise with soft jaws and install pump reservoir.
16. Install pressure union and new O-ring seal in reservoir. Tighten union firmly.
17. Install mounting stud and new O-ring seal in reservoir. Tighten stud securely.
18. Install drive shaft key in slot in shaft. Support shaft on opposite side while installing key. Install reservoir cap.

SLEEVE TYPE PUMP

Disassembly, Fig. 40

1. Drain oil from pump and reservoir. Cap discharge and return line fittings to exclude dirt from pump.
2. Clean pump and mount it in a vise.
3. Remove reservoir.
4. Loosen capscrews at inlet end cap.
5. Remove flow valve spring retainer fitting.

CAUTION: Flow and plunger springs are under pressure. Use care when removing cap and retainer to prevent spring and fitting from escaping due to spring force.

6. Remove flow valve and spring.
7. Remove and disassemble both end caps from inlet cap body and pump housing. Plunger spring will tend to push cylinder blocks out of body. Use care when disassembling.
8. The cylinder blocks will push out of body slightly due to pressure of plunger spring between blocks. Remove cylinder drive blocks and sleeves from pump body as well as cylinder plunger spring.
9. Remove ball bearing retainer ring from housing, using snap ring pliers.
10. Remove shaft and bearing.

Inspection

1. Wipe bearing and shaft assembly with clean, lint-free cloths. Do not soak in cleaning solvent as the lubricants sealed in the bearing may become diluted by solvent.
2. Inspect shaft for wear and check bearing for roughness or noisy operation.
3. If bearing must be replaced, remove shaft key and press bearing from shaft away from splined or serrated end of shaft.
4. Examine retaining ring groove in housing.
5. If ball bearing is to be replaced, support bearing on its inner race and press shaft through bearing until retaining ring stops against inner race of bearing. Retaining ring must always be placed between bearing and splined or serrated end of shaft.
6. Check fit of sleeves in cylinder block bores. Sleeves must slide freely.
7. Examine mating surfaces of sleeves and bores. Heavy scoring, if present, can impair pump efficiency. Cylinder blocks showing such scoring must be replaced. Hairline markings seen on sleeves are normal.
8. Examine flow valve spool and valve liner. Slight hairline scratches are permissible. Burrs from heavy gouges or scratches which may cause flow spool to stick must be removed. This may be done by polishing with a smooth stone.

CAUTION: Do not break sharp edges of spool or liner.

9. Insert flow valve in valve body. By means of a pencil or other such rod which will not mar internal diameter of valve liner, move flow spool back and forth to inspect. On each pass, rotate spool slightly. Spool must slide freely. If spool sticks or drags, remove it from liner. Remove dirt, nicks or burrs, using above caution and check by repeating the foregoing procedure.
10. Examine shaft seal in bearing cap. If worn or damaged, replace seal.

NOTE: Lips of seal must point toward casting. Examine running surfaces of bearing cap and inlet end cap. If heavy scratches or gouges are present or if port edges are damaged, the part should be replaced.

11. Press seal in until shoulder stops against bearing cap casting. Care must be used to see that seal is properly aligned. This operation should be performed in an arbor press.
12. Check pressure relief valve which is located in flow valve spool. The valve must not leak at any pressure below 850 psi. Evidence of leakage

Fig. 40 Sleeve type power steering pump (typical)

Fig. 41 Drive block assembling fixture

Fig. 42 Assembling sleeves in drive cylinder

will be seen at small holes in side of flow spool. If relief valve leaks, disassemble by removing valve seat and checking for dirt or nicks.

13. Clean all valve parts and reassemble, replacing valve seat if nicked or damaged. Check pressure again. If pressure still falls below minimum requirement, disassemble valve again and replace pressure relief spring or place a $\frac{1}{32}$" between spring and ball retainer. To correct pressures exceeding the maximum requirement, remove valve seat and place a $\frac{1}{32}$" washer between valve seat and flow spool body.
14. Examine pump body for signs of unusual wear or damage.

Reassembly, Fig. 40

1. Press drive shaft and bearing into bearing cap. Check rotation of shaft to make certain it turns freely. Use a sleeve which bears against outer race of ball bearing and press subassembly in place.

CAUTION: Make certain that the shaft bearing sub-assembly are properly aligned, otherwise the shaft may push sleeve bearing out of bearing cap or may scratch or mar inside diameter of sleeve bearing.

2. Using assembly fixture (C-3602) shown in Fig. 41, place driven cylinder block (without spline or serration) on fixture.
3. Lubricate (light oil) and insert plunger spring, plunger and seven sleeves in drive block, Fig. 42.
4. Place pump body, square end down, over cylinder drive block and fixture locating pins. Use a pointed probe to align sleeves to a uniform spacing and install the two remaining sleeves.
5. Position drive splined block with serration over sleeves. Sighting through bores in drive block for alignment, lower cylinder block until it engages the two sleeves in the forward position.
6. Again use a pointed probe slightly smaller in diameter than the sleeve bores, Fig. 43, and correct the alignment of sleeves in the 5 and 7 o'clock positions, at the same time guiding cylinder block downward. Continue this procedure to the 4 and 8 o'clock positions until all the sleeves are aligned and engaged. The block may then be pushed in all the way.

CAUTION: Do not force the cylinder block in place. Proper alignment of the block and sleeves will allow the block to be pushed easily into place without excessive pressure. Tighten body to housing.

7. Remove body and cylinder block from fixture, using care to see that blocks are not forced out of body by plunger spring.
8. Assemble a new end cap gasket on pump body. Install end cap on body and tighten capscrews finger tight.
9. Insert a new O-ring in counterbore at flow valve liner in body. Install a new bearing cap gasket, and assemble bearing cap to body.

NOTE: It may be necessary to exert hand pressure on bearing cap to get drive block down into body after bearing cap is seated.

10. Tighten capscrews finger tight. Grip end of pump shaft in vise and rotate pump. Pump should rotate freely without binding. After making sure pump rotates freely, tighten capscrews uniformly to 25 ft-lbs. Check pump again for rotation.
11. Mount pump in vise in vertical position, gripping on bearing hub.
12. Install flow valve with the $\frac{3}{16}$" land down.
13. Place flow valve spring on top of spool. Replace O-ring on flow spring retainer fitting. Compress flow spring with fitting and screw fitting into place. Tighten to 20 ft-lbs.
14. Install and align a new reservoir O-ring on bearing cap. Lubricate O-ring for ease in assembling reservoir. Align reservoir and push it into place, applying force around its outside diameter.

CAUTION: Do not attempt to align or pull reservoir into place on the angular boss with the ¼" capscrew.

15. Install shaft key and pulley. Tighten pulley attaching bolt to 20 ft-lbs.
16. Refill pump with automatic transmission fluid.

Fig. 43 Installing drive block

Chrysler Constant Control Type Gear

The Constant Control Full Time Power Steering consists of a hydraulic pressure pump, a power steering gear and connecting hoses. The power steering gear consists of a gear housing, containing a gear shaft and sector shaft; a power piston with gear teeth milled into the side of the piston which is in constant mesh with the gear shaft sector teeth; and a worm shaft which connects the steering wheel to the power unit piston through a coupling.

Pump Pressure

With pump reservoir filled with oil to the proper level, turn steering wheel several times from one extreme to the other until all air is bled from the system. Air in the system will be indicated by bubbles in the reservoir.

Fig. CC1 Removing or installing valve body assembly

Fig. CC2 Removing valve lever

Fig. CC3 Removing or installing gear shaft cover nut

Connect a pressure gauge between pump and steering gear. Then, with engine idling and steering gear at normal operating temperature, turn steering wheel to either extreme position, hold it momentarily against the stop and note the pressure indicated on the gauge. The pressures that should obtain are as follows:

CHRYSLER	PRESSURE
1966-68	1000-1100
1965 Newport, 300	950-1000
1965 New Yorker	1000-1100

Steering Gear Repairs

Prior to disassembly, clean the gear assembly thoroughly in a suitable solvent. Crocus cloth may be used to remove small nicks and burrs provided it is used carefully. When used on the steering gear valve, use extreme care not to round off the sharp edge portions of the two lands located between the valve drilled holes. Remove and discard all "O" ring seals, using new ones lubricated with petrolatum when reassembling.

Disassemble

1. Drain steering gear through pressure and return connections by turning the steering tube coupling from one extreme of travel to the other.
2. Drive out coupling pin and remove coupling.
3. Remove valve body and three "O" rings, Fig. CC1.
4. Remove valve lever by prying under spherical head, Fig. CC2. *Use care not to collapse slotted end of valve lever as this will destroy bearing tolerances of head.*
5. Remove gear shaft cover nut, Fig. CC3.
6. Rotate worm shaft to full right turn, reverse rotation of worm shaft until piston is at center of travel. Then remove gear shaft and cover, Fig. CC4.
7. Remove steering column support nut, Fig. CC5. Turn worm shaft to full right position to compress parts and back off as necessary to align holes in column support and worm shaft.
8. Enter a piece of drill rod through holes in jacket support and worm shaft to keep parts from turning and remove power train, Fig. CC6.
9. Disassemble power train after removing thrust bearing nut.
10. Remove worm shaft upper oil seal,

Fig. CC4 Removing or installing gear shaft and cover

Fig. CC5 Removing steering column support nut

Fig. CC6 Removing or installing power train

Fig. CC7 Removing worm shaft upper oil seal

Fig. CC8 Installing worm shaft upper oil seal

Fig. CC9 Removing reaction ring from cylinder head

Fig. CC7, and disassemble column jacket support. Reaction seal may be removed from groove in face of jacket support by blowing air pressure into ferrule chamber. Make sure passage from ferrule chamber to upper reaction chamber is unobstructed.

Column Jacket Support, Assemble

Install worm shaft upper oil seal with sealing lip toward bearing, Fig. CC8. Tool C-3650 should be used to drive seal until tool bottoms on casting to obtain proper compression of rubber seal. Lubricate reaction seal and install in groove in face of column jacket support with flat side of seal out.

Cylinder Head

Disassemble—Remove two "O" rings in outer grooves in head. Remove "O" ring in groove in face of cylinder head with air pressure into oil hole located in groove between two "O" ring grooves, Fig. CC9. Replace cylinder head seal if necessary, Fig. CC10. Check oil passage in ferrule for obstruction. Check lands of cylinder head for burrs.

Assemble — Lubricate and install two large "O" rings in grooves on head. Install lower reaction seal in groove in face of head. The small "O" ring for ferrule groove should be installed after worm shaft bearing preload has been established, otherwise "O" ring will be damaged by reaction springs.

Steering Valve

Disassemble — Compress control valve spring and remove spring retainer pin, spring and pressure control piston. Remove valve body (2 screws) from steering valve. Shake out valve piston. If spool valve or valve housing is damaged, replace complete valve assembly. Do not remove valve end plug unless inspection indicates a leak at seal.

Assemble—Fig. CC11. Install steering valve in housing. Valve lever hole should align with steering gear valve lever opening in bottom of valve housing. Valve must fit smoothly in housing without striking or binding. If valve end plug was removed install new seal and tighten plug to 50 lb. ft. torque. Lubricate pressure control valve piston and slide it into valve body (nose end first). Install spring on top of piston. Compress pin and install pin through both holes at top of control valve body. Assemble control valve body to steering valve body and torque attaching screws to 10 lb. ft. Install new copper sealing gasket and fitting in threaded hole on top of valve body and torque to 30 lb. ft.

Gear Shaft

Disassemble — Remove adjusting screw lock nut and unscrew cover from adjusting screw. Remove screw and washer from, "T" slot in end of gear shaft. Remove small "O" ring from top of cover and large "O" ring from base of cover.

Assemble — Place adjusting screw washer over screw and slide both into "T" slot of shaft. Screw cover into adjusting screw until gear shaft bottoms in cover. Install small "O" ring over adjusting screw into position at top of cover. Install lock nut on adjusting screw but do not tighten. Install large "O" ring in groove on lower face of gear cover.

Steering Gear Housing

Disassemble — The equipment shown in Fig. CC12 should be used for this operation. After removing the oil seal snap ring and back-up ring, remove the oil seal by sliding the threaded portion of the tool's adapter over end of gear shaft and install nut section of tool (C-3350) on shaft. Maintain pressure on adapter with

Fig. CC10 Removing cylinder head seal

Fig. CC11 Control valve disassembled

Fig. CC12 Removing gear shaft oil seal

Fig. CC13 Installing gear shaft oil seal

Fig. CC14 Steering gear disassembled

nut of tool while turning adapter, forcing it into seal until it has bottomed in seal. Apply two half rings and retainer over both portions of tool. As hex nut is removed from shaft seal will be pulled from housing.

Assemble—Install gear shaft oil seal in housing (lip of seal toward needle bearing) using Tool C-3350. Place adapter against seal and tool nut on threaded end of gear shaft. Tighten tool nut until adapter shoulder contacts housing, Fig. CC13. Install oil seal back-up ring, oil seal and snap ring.

Power Train, Assemble

Fig. CC14. Position piston assembly on bench with worm shaft up. Slide cylinder head (ferrule up) on worm shaft and against piston flange, making sure gap on worm shaft ring is closed to avoid breaking ring. Lubricate and install in the following order:

1. Lower thrust bearing race (thick).
2. Lower thrust bearing.
3. Lower reaction spring over ferrule.
4. Lower reaction ring with flange up so that ring protrudes through reaction spring.
5. Center bearing race, indexing control hole with hole in center bearing race.
6. Install outer spacer, upper thrust bearing, upper thrust bearing race (thin) and new worm shaft thrust bearing nut.
7. Tighten nut as follows: Turn worm shaft counterclockwise ½ turn and hold shaft in this position while tightening nut to 10 lb. ft. torque.

If worm shaft is turned more than ½ turn cylinder head seal will clear oil ring on worm shaft.

8. Always check position of worm shaft oil ring before bottoming cylinder head against worm piston shoulder to avoid damaging oil ring.
9. Rotate worm center bearing race several turns to position all parts; then loosen adjusting nut.
10. Retighten worm bearing adjusting nut to give a bearing torque of 8 to 16 oz. Check by placing rounds of cord around center bearing race. Make a loop in one end and hook the loop of a spring scale in the cord loop. Pulling on cord will cause bearing race to rotate.
11. If adjusting nut is tightened properly, reading on scale will be 8 to 16 oz. Stake flange of adjusting nut into depression in worm shaft to lock securely.
12. The 8 to 16 oz. torque must remain after nut is locked.
13. Install center bearing spacer over bearing race to engage dowel pin with slot in center bearing race.

Make sure valve lever hole in center bearing race and center spacer are properly aligned.

14. After installing balance of parts, align parts of power train so that valve lever hole in center bearing spacer is 90 deg. counterclockwise

Fig. CC15 Alignment of bearing spacer and center bearing race

Fig. CC16 Installing valve lever

from piston rack teeth and lock all parts to worm shaft by entering a drill rod through jacket support and worm shaft holes.

Steering Gear, Assemble

Service Note

1963-65: The master serration on the power steering gear worm shaft spline, used for centering the steering shaft coupling on these models, is machined after the steering gear is completely assembled.

Should it become necessary to replace a power steering gear worm shaft and piston assembly, a master serration should be filed on the spline of the worm shaft, since the replacement part does not have a master serration machined in the spline.

To file a master serration on a worm shaft spline, the power steering gear must be completely assembled and the worm shaft centered in its travel. Then, with the steering gear in its normal upright position, remove one tooth of the spline, at the 12 o'clock position, with a suitable file.

1. With steering gear housing fastened in holding fixture in approximate car position, lubricate bore of housing with petrolatum and install power train assembly (Fig. CC5) with center bearing spacer valve lever hole in "up" position to line up with lever clearance hole in gear housing.
2. Place a .0015" feeler gauge to cover aligning notch in gear housing to protect "O" ring sealer when installing gear train. Make sure cylinder head is bottomed on housing shoulder. Do not remove power train locking pin until all parts are positioned in steering gear housing.
3. Align valve lever hole in center bearing spacer exactly with clearance hole in housing with aligning tool, Fig. CC15. *Tool should not be removed until spanner nut is securely tightened.*
4. Install column support nut and tighten to 150 lb. ft. torque (see Fig. CC5).
5. Set piston at center of travel and install gear shaft and cover so that sector teeth index with piston rack teeth. Install cover nut and torque to 100 lb. ft. (see Fig. CC3).
6. Install valve lever (double bearing end first) into center bearing spacer through hole in steering housing so that slots in valve lever are parallel to worm shaft in order to engage anti-rotation pin in center bearing race, Fig. CC16.
7. Install valve body on housing, making sure valve lever enters hole in piston (see Fig. CC1). Tighten screws to 30 inch lbs.

Tests and Adjustments

1. Fill reservoir to level mark.
2. Connect test hoses to hydraulic pump on car with pressure gauge installed between pump and steering gear to register pressures.
3. Start engine and operate at idle to bring steering gear to normal operating temperature.
4. Expel all air from system by turning steering wheel several complete turns from one extreme to the other.
5. Refill reservoir.
6. Turn gear shaft adjusting screw outward to assure no mesh adjustment preload for this phase of the test.
7. Tighten steering valve body attaching screws to a torque of 7 lb. ft.
8. Apply oil pressure to complete unit and position steering valve by tapping lightly on one of the pressure control valve screws or on valve end plug to position valve up or down on housing to give equal gear shaft torque within 5 lb. ft., not to exceed 20 lb. ft. in either direction when gear shaft is turned slowly. *Perform this operation carefully or a lockup will occur in steering gear.*
9. With gear shaft on center, tighten gear shaft adjusting screw until backlash just disappears. Tighten 1¼ turns from this position and, while holding adjusting screw in this position, tighten lock nut.
10. Turn off hydraulic power unit.
11. Operate unit manually for a minimum of 180 deg. from center in either direction, measured at worm shaft.
12. Turn on hydraulic power unit.
13. Operate unit through a minimum of one complete cycle. Operate unit through another cycle, this time holding unit at extreme travel in each direction while watching oil pressure gauge. Gauge reading should be equal in each direction; if not it indicates excessive internal leakage.
14. With oil temperature between 150 to 170 deg. (checked with thermometer in reservoir) oil pressure should be 850 to 950 psi for satisfactory steering operation.
15. With gear shaft on center (plus or minus 2 deg.) readjust gear shaft backlash. Tighten adjusting screw until backlash disappears; continue to tighten ⅜ to ½ turn from this position and tighten lock nut to 50 lb. ft. torque, Fig. CC17.
16. Start from a point at least one full turn of the worm shaft either side of center.
17. The torque at gear shaft required to turn unit through center at 2 rpm in each direction should not exceed 20 lb. ft. and not vary more than 5 lb. ft. from left to right.
18. Position steering valve to obtain equal torque and tighten valve body attaching screws to maintain this setting.

Fig. CC17 Adjusting gear shaft adjusting screw

19. With unit under power, but with no load, the torque required to rotate the worm shaft through an included angle at 180 deg. (90 deg. either side of center) should be 5 to 9 inch lbs.
20. Disconnect test equipment.
21. Place steering gear worm at center of travel and install worm connector.
22. Install unit in car.

TROUBLE SHOOTING

Hard Steering

1. Tires not properly inflated.
2. Low oil level in reservoir.
3. Loose pump belt.
4. Oil on pump belts.
5. Steering linkage needs lubrication.
6. Power steering pump output low.
7. Cross shaft adjustment too tight.
8. Pressure control valve stuck in closed position.
9. External oil leaks.
10. Defective or damaged valve lever.
11. Dirt or chips in steering gear.
12. Damaged column support worm shaft bearings.
13. Damaged thrust bearings or excessive preload adjustment.
14. Rough or hard to turn worm and piston assembly.
15. Excessive internal leakage.

Poor Recovery From Turns

1. Tires not properly inflated.
2. Steering linkage binding.
3. Improper wheel alignment.
4. Damaged or defective steering tube bearings.
5. Steering column jacket and steering gear not properly aligned.
6. Improper cross shaft mesh adjustment.
7. Pressure control valve piston stuck open.
8. Column support spanner nut loose.
9. Defective or damaged valve lever.
10. Improper worm thrust bearing adjustment.
11. Burrs or nicks in reaction ring grooves in cylinder head or column support.
12. Defective or damaged cylinder head worm shaft seal ring.
13. Dirt or chips in steering gear unit.
14. Rough or catchy worm and piston assembly.

Self-Steering or Leads to Either Side

1. Tires not properly inflated.

2. Improper wheel alignment.
3. Steering wheel off center when car is traveling straight ahead.
4. Valve body out of adjustment.
5. Valve lever damaged.
6. Column support spanner nut loose.

Temporary Increase In Effort When Turning Steering Wheel

1. Low oil level.
2. Loose pump belt.
3. Oil on pump belts.
4. Binding steering linkage.
5. Engine idle too slow.
6. Defective power steering pump.
7. Air in system.
8. External adjustment.
9. Improper cross shaft adjustment.
10. Excessive internal leakage.

Excessive Steering Wheel Free Play

1. Improper cross shaft adjustment.
2. Column support spanner nut loose.
3. Improper worm thrust bearing adjustment.

Lack of Assistance In One Direction

1. Oil leaking past worm shaft cast iron seal ring or ferrule "O" ring.

Lack of Assistance In Both Directions

1. Broken "O" ring on worm piston.
2. Piston end plug loose.
3. Pump belt slipping.
4. Pump output low.

Noises

1. Buzzing noise in neutral only is caused by sticking pressure control valve.
2. Noisy power pump.
3. Damaged hydraulic lines.
4. Pressure control valve sticking.
5. Improper sector shaft adjustment.
6. Air in system.

Ford Torsion Bar Type Gear—to 1964

Description

The power steering gear is designed with all components in one housing, Fig. F1. This makes possible internal oil passages between the valve and cylinder, thus eliminating all external lines and hoses, except the pressure and return hoses between the pump and gear.

The power cylinder is an integral part of the housing. The piston is of the double acting type in that oil pressure may be applied to either side of the piston. The one-piece piston and power rack is meshed to the sector shaft.

The hydraulic control valve, actuated by the torsion bar, is composed of a sleeve and valve spool. The spool is an open center type "4-way" valve. The spool is held in neutral position by the torsion bar and spool actuator. The spool is actuated by the torsion bar. The amount of twisting of the torsion bar depends on the reaction load of the worm and ball nut. The greater the load the greater the twisting of the torsion bar. The torsion bar moves the valve spool which allows pressure to be directed to either side of the power piston, depending upon directional rotation of the steering wheel, to give power assist.

Pump Pressure

With pump reservoir filled with oil to the proper level, turn steering wheel several times from one extreme to the other until all air is bled from the system. Air in the system will be indicated by bubbles in the reservoir.

Connect a pressure gauge between pump and steering gear. Then, with engine idling and steering gear at normal operating temperature, turn steering wheel to either extreme position, hold it momentarily against the stop and note the pressure indicated on the gauge. The pressures that should obtain are as follows:

Car	Year	Pressure
Lincoln	1963-64	1120-1250
Thunderbird	1963-64	950-1100

Disassemble Steering Gear

1. Remove steering shaft coupling.
2. Remove snap ring and cylinder cap from piston bore; then remove cylinder cap "O" ring.
3. Turn steering shaft all the way to stop and back off 2⅛ turns.
4. Loosen sector shaft adjusting screw, remove cover screws and tap sector shaft out of housing.
5. Remove adjusting screw from cover.
6. Working through sector shaft bore and piston rack, pry piston out.
7. Remove piston "O" ring and piston rack bore "O" ring.
8. Loosen valve sleeve lock screw.
9. Remove valve spool adjuster cap and remove "O" ring from cap.
10. Remove thrust bearing lock nut and control valve sleeve adjuster nut.
11. Remove torsion bar and sleeve assembly by tapping on lower end of torsion bar.
12. Remove sector shaft seal retaining ring and gear housing snap ring.

Disassemble Torsion Bar and Sleeve

1. Position ball nut in vise, using cloth to protect ball nut.
2. Remove valve spool sleeve from torsion bar, and "O" ring from sleeve.
3. Remove adjuster lock nut from lower end of torsion bar. Then remove valve spool adjuster from torsion bar and "O" ring from adjuster.
4. Remove torsion bar, valve spool and actuator from worm shaft.
5. Remove worm thrust bearing and cup from gear housing.
6. Separate valve spool and actuator from torsion bar, using turning motion.
7. Remove snap ring and take valve spool from actuator.
8. Do not disassemble ball nut unless there is evidence of binding or rough spots.
9. Inspect all parts for damage and replace as necessary.

Assemble Torsion Bar and Sleeve

1. Install torsion bar bearing in sleeve.
2. Install torsion bar bearing seal.
3. Install snap ring and check bearing rotation.
4. Check fit of worm gear outer race to insure that it is a hand fit. Then install bearing and race on worm shaft.
5. Install valve spool on actuator and retain with new snap ring. Check valve spool for free rotation.
6. Install torsion bar spring and actuator on torsion bar. *Turn lower shaft so that two identifying punch marks are aligned.* Hold assembly together and insert torsion bar into worm, *aligning blind spline on torsion bar with scribed line on end of worm.* The torsion bar is properly installed when the valve spool bottoms against upper bearing and cup.
7. Install "O" ring on valve spool adjuster and install adjuster on torsion bar, *but do not tighten.* Install lock nut. Lubricate lip of torsion bar seal with automatic transmission fluid.
8. Install valve sleeve over valve spool until worm gear upper race is seated in recess of sleeve. Install new "O" ring on sleeve.

Steering Gear Housing

1. Inspect housing for cracks and stripped threads, and mating surfaces for burrs.
2. Check fluid passages for obstruction or leakage.
3. Inspect housing bore. If scored or worn, replace housing.
4. Check sector shaft bushings in housing for wear. If worn replace bushings.
5. Remove lower worm bearing cup and inspect for wear.

Assemble Steering Gear

1. Align slot in sleeve with lock screw in housing and install torsion bar and sleeve assembly in housing. Tap on sleeve until it bottoms. Tighten lock screw to a torque of 15-20 lb. ft.
2. Install preload adjusting nut and lock nut. Check worm bearing preload with special tool and spring scale, Fig. F2. Adjust preload to ½ to ⅔ lb. on spring scale. Always make final adjustment on the tighten stroke of adjuster.
3. Install valve spool centering wrench, Fig. F3, on spool adjuster and center valve spool until only the valley be-

Fig. F1 First type torsion bar power steering gear. Lincoln to 1964

Fig. F2 Checking worm bearing preload

tween the lands can be seen through the pressure port. Hold torsion bar with tool shown in Fig. F2 while turning centering wrench. Lock centering screw. This is only a preliminary adjustment; make final adjustment on car.

4. Center ball nut with centerline of sector shaft opening.
5. Install "O" ring in piston rack bore of housing and lubricate.
6. Carefully hone all edges of piston rack teeth with a hand stone to prevent cutting piston rack bore "O" ring during installation.
7. Install new "O" ring on piston and install piston in housing. Align center rack teeth with sector bore in housing (3rd groove in rack).
8. Grease splines on sector shaft and install. Make sure sector shaft is centered by installing tool shown in Fig. F2 on torsion bar and rotate worm shaft. Count turns from one stop to the other. There should be at least four turns. If less than four turns remove sector shaft and reinstall correctly.
9. Install sector shaft seal and snap ring.
10. Install sector shaft adjusting screw with proper shim in slot in sector shaft.
11. Place housing cover with new gasket

Fig. F3 Locking valve spool centering screw

over adjusting screw and turn screw until cover is seated. Install and torque cover screws 15-50 lb. ft.

12. Adjust sector shaft by centering the gear and adjusting the mesh load to obtain 1 to 1½ lbs. on spring scale as shown in Fig. F2. Greater load should be on high point rather than at end of travel.
13. Check piston rack backlash.
14. Install new "O" ring on cylinder end cap and install cap. Retain cap in cylinder with snap ring.
15. Install gear assembly in car and center valve spool as outlined below.

Centering Valve Spool

Start engine and rotate steering wheel several times to bring oil up to normal operating temperature.

With a spring scale on the rim of the steering wheel, and steering gear centered, read the force necessary to make a left and right hand turn. The difference should not be more than ½ lb. If more than ½ lb. difference remove adjuster cap, loosen lock nut and turn adjuster in direction of the light reading. For example, if the steering wheel requires less force to turn to the left than to the right, turn the adjuster in the same direction (left). Recheck reading and lock jam nut. Install cap.

TROUBLE SHOOTING

Refer to later type Ford unit which follows:

Ford Torsion Bar Power Steering-from '65

Description

The power steering unit, Fig. F4, is a torsion bar type of hydraulic-assisted system. This system furnishes power to reduce the amount of turning effort required at the steering wheel. It also reduces road shock and vibrations.

The unit includes a worm and one piece rack-piston which is meshed to the gear teeth on the steering sector shaft. The unit also includes a hydraulic valve, valve actuator, input shaft and torsion bar assembly which are mounted on the end of the worm shaft and operated by a twisting action of the torsion bar.

The gear unit is designed with the one piece rack-piston, worm and sector shaft in the one housing and the valve spool in an attaching housing. This makes possible internal fluid passages between valve and cylinder, thus eliminating all external lines and hoses except the pressure and return hoses between pump and gear.

Fig. F4 Ford (2nd type from 1965) power steering gear disassembled

Fig. F5 Adjusting mesh load

Fig. F6 Ball nut and valve housing disassembled

The power cylinder is an integral part of the gear housing. The piston is double acting in that fluid pressure may be applied to either side of the piston.

A selective metal shim, located in the valve housing of the gear is for the purpose of tailoring the steering gear efforts. If efforts are not satisfactory they can be changed by increasing or decreasing shim thickness as follows:

Efforts heavy to the left—increase shim thickness. Efforts light to the left—decrease shim thickness. A change of one shim size will increase or decrease steering efforts approximately 1½ inch-lbs. Shims are available in the following thicknesses: (Do not use more than one shim.)

.0057 to .0063″
.0077 to .0083″
.0097 to .0103″
.0117 to .0123″
.0137 to .0143″

Operation

The operation of the hydraulic control valve spool is governed by the twisting of a torsion bar. All effort applied to the steering wheel is transmitted directly through the input shaft and torsion bar to the worm and piston. Any resistance to the turning of the front wheels results in twisting of the bar. The twisting of the bar increases as the front wheel turning effort increases. The control valve spool, actuated by the twisting of the torsion bar, directs fluid to the side of the piston where hydraulic assistance is required.

As the torsion bar twists, its radial motion is transferred into axial motion by three helical threads. Thus, the valve is moved off center, and fluid is directed to one side of the piston or the other.

Power Steering Pump

The power steering pump is a belt-driven slipper type pump which is integral with the reservoir. It is constructed so that the reservoir is attached to the rear side of the pump housing front plate and the pump body is encased within the reservoir.

Pump pressure is 1000 to 1150 psi. If pump is defective, replace it with a new pump as individual parts are not furnished.

IN-CAR ADJUSTMENTS & REPAIRS

Valve Spool Centering Check

1. Install a 2000 psi pressure gauge in pressure line between pump outlet port and steering gear inlet port. *Make sure that valve on gauge is in fully open position.*
2. Check fluid level in reservoir and replenish as required.
3. Start engine and cycle steering wheel from stop-to-stop to bring steering lubricant up to normal operating temperature. Stop engine and recheck reservoir. Add fluid as necessary.
4. With engine running at a fast idle speed (1000 rpm) and steering wheel centered, attach an inch-pound torque wrench to steering wheel retaining nut. Apply sufficient torque to wrench in each direction (either side of center) to get a gauge reading of 250 psi.
5. The torque reading should be the same in both directions when 250 psi is reached. If the difference between readings exceed 4 inch-lbs, the steering gear must be removed and the valve centering shim removed from the valve housing and a thicker or thinner shim installed. *Only one shim is to be used.* If the steering effort is heavy to the left the shim thickness should be increased. Shim thickness should be decreased if the steering effort is light to the left.

NOTE: The "out-of-car" procedure for valve centering check is the same as for the "in-car" except the torque and simul-

Fig. F7 Valve housing disassembled

Fig. F8 Steering gear housing disassembled

Fig. F9
Assembling piston on worm shaft

taneous pressure reading must be made at the right and left stops instead of either side of center.

Steering Gear Adjustments

Preload (thrust bearing adjustment) and worm-to-rack preload cannot be changed in service. The only adjustment that can be performed is the total over-center position load to eliminate excessive lash between sector and rack teeth.

1. Disconnect pitman arm from sector shaft.
2. Disconnect fluid return line at reservoir and cap reservoir return line pipe.
3. Place end of return line in a clean container and cycle steering wheel in both directions as required to discharge fluid from gear.
4. Remove ornamental cover from wheel hub and turn steering wheel 45° from left stop.
5. Using an inch-lb torque wrench on steering wheel nut, determine torque required to rotate shaft slowly through an approximately ⅛ turn from the 45° position.
6. Turn steering gear back to center, then determine torque required to rotate shaft back and forth across center position.
7. Loosen adjuster nut and turn adjusting screw in until reading is 8 to 9 inch-lbs greater than torque 45° from stop. Tighten lock nut while holding screw in place, Fig. F5.
8. Recheck readings and replace pitman arm and steering wheel.
9. Connect fluid return line and replenish reservoir.

STEERING GEAR REPAIRS

Disassembly

1. Hold steering gear over drain pan in an inverted position and cycle input shaft six times to drain remaining fluid from gear.
2. Remove lock nut and brass thrust washer from adjusting screw.
3. Turn input shaft to either stop, then turn it back approximately 1¾ turns to center the gear.
4. Remove two sector shaft cover screws and identification tag.
5. Tap lower end of sector shaft with a soft-faced hammer to loosen it, then lift cover and shaft from housing as a unit. Discard O-ring.
6. Turn sector shaft cover counterclockwise off adjuster screw.
7. Remove four valve housing attaching bolts. Lift valve housing from gear housing while holding piston to prevent it from rotating off worm shaft. Remove valve housing and lube passage O-rings and discard.
8. Stand valve body and piston on end with piston end down. Rotate input shaft counterclockwise out of piston, allowing balls to drop into piston.
9. Place a cloth over open end of piston and turn it upside down to remove balls.
10. Remove ball guide (2 screws) from ball nut and remove clamp and guides, Fig. F6.
11. Hold valve body in a fixture and remove lock nut and retaining nut.
12. Carefully slide input shaft, worm and valve out of valve housing.

CAUTION: Due to the close diametrical clearance between valve spool and housing, the slightest cocking of the spool may cause it to jam in housing.

13. Remove shim from valve housing.

Valve Housing, Replace

1. Referring to Fig. F7, remove dust seal and snap ring.
2. Invert housing and, from opposite seal end, gently tap bearing and seal out of housing.

CAUTION: Exercise care when inserting and removing tool to prevent damage to valve bore in housing.

3. Remove oil inlet and outlet tube seats with "EZ-out" if damaged.
4. Coat tube seats with vaseline and position them in housing. Install and tighten tube nuts to press seats to proper location.
5. Coat bearing and seal surface in housing with a film of vaseline.
6. Position bearing in valve housing. Seat bearing in housing, making sure that bearing is free to rotate.
7. Dip new oil seal in gear lube. Then place it in housing with metal side of seal facing outward. Drive seal into housing until outer edge of seal does not quite clear snap ring.
8. Place snap ring in housing. Then drive on ring until snap ring seats in its groove to locate seal properly.
9. Place dust seal in housing with dished side (rubber side) facing out. Drive dust seal in place so that it is located behind undercut in input shaft when it is installed.

Worm & Valve, Replace

1. Remove snap ring from actuator.
2. Slide control valve spool off worm shaft, Fig. F6.
3. Install valve spool evenly and slowly with a slight oscillating motion into flanged end of valve housing with valve identification groove between spool lands outward. Check for freedom of valve movement within housing working area. Spool should enter housing bore freely and fall by its own weight.
4. If valve spool is not free, check for burrs at outward edges of working lands in housing and remove with a hard stone.
5. Check valve for burrs and, if necessary, stone valve in a radial direction only.
6. Remove valve spool from housing.
7. Slide spool onto worm shaft, making sure that groove in spool annulus is toward worm.
8. Install snap ring to retain spool.
9. Check clearance between spool and snap ring, which should be .002 to .005″. If not within these limits select a snap ring that will allow .003″ clearance.

Piston & Ball Nut, Replace

1. Remove teflon ring and O-ring from piston and ball nut, Fig. F6.
2. Dip a new O-ring in gear lube and install on piston and ball nut.
3. Install new teflon ring on piston and ball nut, being careful not to stretch it any more than necessary.

Gear Housing

DISASSEMBLE:

1. Remove snap ring and spacer washer, Fig. F8, from lower end of gear housing.
2. Remove lower seal from housing and lift spacer washer from housing.
3. Remove upper seal in same manner.
4. Press bushing from housing if worn or damaged (2 bushings on Lincoln and T-Bird). Press new bushing into housing.
5. Dip both sector shaft seals in gear lube.
6. Position sector shaft inner seal (widest one) into housing with lip facing inward. Place a spacer washer on top of it.
7. Place outer seal in housing with lip facing inward. Place spacer washer on top of it and press into place.
8. Position snap ring in housing and press it in place to properly locate seals and engage snap ring in the groove.

ASSEMBLE:

1. Place required thickness valve spool centering shim in housing, Fig. F6. *Use one shim only.*
2. Install worm and valve in housing.
3. Install retaining nut in housing and torque to 55-65 ft-lbs.
4. Install lock nut and tighten to 20-30 ft-lbs.
5. Place piston on bench with ball guide holes facing up. Insert worm shaft into piston so that first groove is in alignment with hole nearest to center of piston, Fig. F9.
6. Place ball guide into piston. Place 27 balls in guide, turning worm

clockwise (viewed from input end of shaft). If all balls have not been fed into guide upon reaching right stop, rotate input shaft in one direction and then in the other while installing balls. After balls have been installed, do not rotate input shaft or piston more than 3½ turns off the right stop to prevent balls from falling out of circuit.
7. Secure guides to ball nut with clamp.
8. Position new lube passage O-ring in counterbore of gear housing.
9. Apply vaseline to teflon seal.
10. Place a new O-ring on valve housing.
11. Slide piston and valve into gear housing, being careful not to damage teflon seal.
12. Align lube passage in valve housing with one in gear housing, and install but do not tighten attaching bolts at this time.
13. Rotate ball nut so that teeth are in same plane as sector teeth. Tighten four valve housing attaching bolts.
14. Position sector shaft cover O-ring in gear housing. Turn input shaft as required to center piston.
15. Apply vaseline to sector shaft journal, then position sector shaft and cover into gear housing. Install identification tag and air conditioner line mounting bracket (if so equipped) and two sector shaft cover bolts.
16. Attach an inch-lb torque wrench to input shaft and adjust mesh load as outlined previously.

TROUBLE SHOOTING

Hard Steering

1. Low or uneven tire pressure.
2. Improper gear adjustment.
3. Improper wheel alignment.
4. Low fluid level.
5. Twisted or bent suspension parts, frame and linkage components.
6. Tight wheel bearings.
7. Steering spindle bent.
8. Pump belt out of adjustment.
9. Pump output low.
10. Air in system.
11. Valve spool out of adjustment.
12. Valve spool sticking.
13. Steering linkage binding.

Hard Steering Straight Ahead

1. Steering adjustment too tight.
2. Steering gear shaft binding.

Hard Steering While Turning or Parking

1. Oil level low.
2. Pump pressure low.
3. Pressure loss in steering gear due to leakage past "O" rings.
4. Pressure loss between valve spool and sleeve.
5. Pressure loss past piston ring or scored housing bore.

Loose Steering

1. Loose wheel bearings.
2. Loose tie rod ends or linkage.
3. Worn ball joints.
4. Worn suspension parts.
5. Insufficient mesh load.
6. Insufficient worm bearing preload.
7. Valve spool out of adjustment.

Erratic Steering

1. Oil or brake fluid on brake lining.
2. Out of round brake drums.
3. Improperly adjusted brakes.
4. Under-inflated tires.
5. Broken spring or other details in suspension system.
6. Improper caster adjustment.
7. Fluid level low.

Binding or Poor Recovery

1. Steering gear shaft binding.
2. Steering gear out of adjustment.
3. Steering linkage binding.
4. Valve spool binding due to dirt or burred edges.
5. Valve spool out of adjustment.
6. Interference at sector shaft and ball stud.

Loss of Power Assist

1. Pump inoperative.
2. Hydraulic lines damaged.
3. Power cylinder damaged.
4. Valve spool out of adjustment.

Loss of Power Assist In One Direction

1. Valve spool out of adjustment.

Noisy Pump

1. Air being drawn into pump.
2. Lines touching other parts of car.
3. Oil level low.
4. Excessive back pressure caused by obstructions in lines.
5. Excessive wear of internal parts.

Poor Return of Steering Gear to Center

1. Valve spool sticking.
2. Valve spool out of adjustment.
3. All items given under "Binding or Poor Recovery".

Steering Wheel Surge While Turning

1. Valve spool sticking.
2. Excessive internal leakage.
3. Belt slippage.

Saginaw Rotary Valve Type Gear

DESCRIPTION

This type power steering gear, Fig. SR1, operates entirely by displacing oil to provide hydraulic pressure assists only when turning. As the entire gear assembly is always filled with oil, all internal components of the gear are immersed in oil, making periodic lubrication unnecessary. In addition this oil acts as a cushion to absorb road shocks that may be transmitted to the driver.

The steering shaft, hydraulic valve, worm and rack piston nut are all in line, making a compact and space saving steering gear. All oil passages are internal except the pressure and return hoses between gear and pump.

MAINTENANCE

Four factors affect power operation of the steering system: fluid level and condition, drive belt tension, pump pressure and steering gear adjustment. These should always be checked before any major service operations are performed.

Conditions such as, hard or loose steering, road shock or vibrations are not always due to steering gear or pump, but are often related instead to such factors as low tire pressure and front end alignment. These factors should be checked and corrected before any adjustment of the steering gear is made.

Checking Fluid Level

1. Run engine to normal operating temperature, then shut it off. Remove reservoir filler cap and check oil level on dipstick. Level should be up to "Full" mark on dipstick.
2. If level is low, add power steering fluid to proper level on dipstick and replace filler cap. *NOTE—When adding less than one pint of fluid, it is permissible to use automatic transmission fluid. When adding larger quantities or when making a complete fluid change, it is recommended that special power steering fluid be used.*
3. When checking fluid level after system has been serviced, air must be bled from the system as follows:

Bleeding System

1. With wheels turned all the way to the left, add the recommended fluid to the "Add" mark on dipstick.
2. Start engine. While running at fast idle, recheck fluid level and, if necessary, add fluid to the "Add" mark on dipstick.
3. Bleed system by turning wheels from side to side without hitting stops. Maintain fluid level just above internal pump casting. Fluid with air in it will have a light tan appearance. This air must be eliminated from fluid before normal steering action can be obtained.
4. Return wheels to center position and continue to run engine for two or three minutes, then shut it off.
5. Road test vehicle to make sure steering functions normally and is free from noise.
6. Recheck fluid level, making sure level is at the "Full" mark.

Checking Pump Pressure

With pump reservoir filled with oil to

Fig. SR1 Saginaw rotary valve power steering gear

the proper level, turn steering wheel several times from one extreme to the other until all air is bled from the system. Air in the system will be indicated by bubbles in the reservoir.

Connect a pressure gauge between pump and steering gear. Then, with engine idling and steering gear at normal operating temperature, turn steering wheel to either extreme position, hold it momentarily against the stop and note the pressure indicated on the gauge. The pressures that should obtain are as follows:

	PRESSURE
BUICK	
1963-68	1100-1200
BUICK SPECIAL	
1964-68	1100-1200
1963	800-900

Gear Adjustments On Car

When the steering gear is thought to be out of adjustment, a quick check can be made by moving the steering wheel back and forth with short slow motions at the "on-center" position with engine shut off. Excessive looseness felt or heard indicates that either the pitman shaft or the thrust bearing requires adjustment. These adjustments can be made on the car as follows:

THRUST BEARING PRELOAD

1. Remove pitman arm from drag link with a suitable puller.
2. Check for any distortion or binding in flexible coupling, and correct as necessary.
3. Turn steering wheel two turns "off center" (just away from stops) and use a spring tension scale with a piece of tag wire or string to measure pull on steering wheel through an arc not exceeding one inch. Total pull should be between 4 and 12 ounces.
4. If "off-center" pull is greater or less than specified, loosen adjuster plug lock nut and back off adjuster ⅛ turn, using a suitable spanner wrench.

NOTE—*If position of holes in adjuster plug is such that there is insufficient clearance for use of spanner wrench, insert a No. 10 bolt ¾" long in one of the adjuster plug holes and rotate flexible coupling until lower flange contacts bolt. Then back off adjuster plug ⅛ turn.*

5. Recheck steering wheel pull with wheel two turns off center.
6. Adjust preload by tightening adjuster plug to obtain 2 to 6 ounces (at rim of steering wheel) in excess of total drag that was measured with adjuster plug backed off ⅛ turn.
7. Tighten adjuster plug lock nut and recheck preload to insure that plug did not move when tightened.

WORM & BALL PRELOAD

1. Locate center of steering wheel travel and turn steering wheel ½ turn "off-center".
2. With wheel in this position, measure and record total pull through an arc not exceeding one inch. Due to worm and ball preload, the total pull should be 2 to 8 ounces in excess of two turns "off-center" pull previously recorded.
3. If total pull is less than one ounce or more than nine ounces in excess of the two turns "off-center" pull, steering gear must be removed and disassembled for replacement of worm shaft balls.
4. Check for roughness in worm and rack-piston by turning wheel between ¼ turn and 1 turn "off-center" on each side. Noticeable roughness also requires worm replacement.

WORM SHAFT END PLAY

1. Find exact center of steering wheel travel. Tight spot due to pitman shaft should extend for ¼ turn to either side.

Fig. SR2 Power steering gear disassembled

2. With wheel "on-center", measure and record total pull through an arc of three inches or less.
3. Reading should not be more than 36 ounces, but should be at least eight ounces (never more than 20) more than a reading taken ½ turn off-center.

NOTE—*On new steering gears, the factory setting with ball bearing preloads and a new seal drag may cause total pull to be as high as 40 ounces. Within the first 100 miles of operation, the seals seat themselves and the ball bearings polish the rack-piston and worm shaft grooves enough to meet the service specifications.*

4. If pitman shaft end play is not within limits, it should be adjusted so that on-center preload is 16-18 ounces more than the ½ turn off-center load but still not more than 36 ounces. Adjust by loosening lock nut and turning adjusting screw as required. Recheck pull after tightening lock nut.
5. Check for rough spots in pitman shaft sector and power piston rack by turning wheel between ¼ turn to the right and ¼ turn to the left. A visual inspection of gear teeth will reveal necessary correction if rough spots are found. Remember, however, teeth are not absolutely smooth but are machined to hold lubricant.

STEERING GEAR

Disassemble

1. Referring to Fig. SR2, position gear in vise with gear housing end plug facing up.
2. Rotate gear housing end plug retaining ring so that one end of ring is over hole in housing. Spring one end of ring with a punch to allow screwdriver to be inserted to lift ring out, Fig. SR3.
3. Rotate coupling flange counterclockwise until rack-piston just forces end plug out of housing. Remove plug from housing. *CAUTION—Do not rotate any further than necessary or balls will fall out of their circuit and pitman shaft teeth and rack-piston will become disengaged.*
4. Remove rack-piston end plug, using a ½" square drive. *NOTE—To make removal easier, tap rack-piston end plug with a plastic mallet to unseat threads. This is important as end plug is tightened to 50 ft-lbs during assembly and could break during removal if not handled carefully.*
5. Remove lock nut from pitman shaft adjuster screw and discard.
6. Remove four side cover retaining screws and washers from cover.
7. Rotate pitman shaft adjuster screw with an Allen wrench until side cover is lifted free of housing.
8. Separate side cover from pitman shaft; discard side cover O-ring seal.
9. Turn coupling flange until pitman shaft teeth are centered in housing.
10. Tap end of pitman shaft with a soft mallet and slide pitman shaft out of housing.
11. Remove housing end plug O-ring seal and discard.
12. Insert Rack-Piston Arbor into rack-piston against end of worm, Fig. SR4. Turn coupling flange counterclockwise, while holding tool tightly against worm, to force rack-piston onto arbor, and remove rack-piston from gear housing.
13. Remove stub shaft-to-coupling flange retaining screw and remove flange.
14. Remove adjuster plug lock nut by breaking it loose with hammer and punch, and remove lock nut from housing.
15. Loosen adjuster plug and remove from housing, Fig. SR5.
16. Remove valve assembly by grasping stub shaft and pulling out.
17. Remove worm, lower thrust bearing and races from upper end of housing.

Replacing Valve Spool Dampener "O" Ring (Only If Gear Squawks)

The rotary valve assembly includes the valve body, valve spool and stub shaft assembly. All these parts are precision units and are hydraulically balanced at

the factory. Under no circumstances are parts in this unit to be replaced or interchanged with other parts or units. If unit parts are scored or damaged the entire rotary valve assembly is to be replaced.

1. To replace the valve spool dampener "O" ring, work spool spring into bearing diameter of stub shaft and remove spool spring.
2. Tap end of stub shaft gently against workbench to remove valve spool. *The diametrical clearance between the valve body and spool may be as low as .0004". The slightest cocking of the spool may jam it in the valve body.*
3. Remove valve spool dampener "O" ring.
4. Install new "O" ring in valve spool groove, then lubricate seal in automatic transmission fluid. Do not allow seal to twist in groove.
5. With notch end of spool towards valve body, install spool, aligning spool notch with pin in stub shaft, Fig. SR6.

6. *Because of the small clearance between spool and valve body, extreme care must be taken when assembling these parts. Push spool evenly and slowly with a slight oscillating motion until spool reaches drive pin. Before pushing spool completely in, make sure dampener "O" ring seal is evenly distributed in spool groove. Slowly push spool completely in, with extreme care taken not to cut or pinch "O" ring seal.*

7. Slide spool spring over stub shaft and work spring into position.

Disassemble Rotary Valve

1. Work spool spring onto bearing diameter of stub shaft and remove spool spring.
2. Tap end of stub shaft gently against workbench to remove valve spool.

Because of the slight clearance between valve body and spool, the slightest cocking of spool may jam it in valve body. If slight cocking occurs, make a gentle attempt to reverse removal procedure. If this does not free spool, it has become cocked in valve body bore and may be removed later.

3. Remove and discard valve spool dampener "O" ring.
4. Remove stub shaft, torsion bar (small diameter bar extending through stub shaft) and valve cap by tapping end of torsion bar lightly with a plastic hammer. This will dislodge cap from valve body cap pin, Fig. SR6. Do not disassemble stub shaft as these parts are pinned together and serviced only as an assembly.
5. If valve spool has become cocked as mentioned above, first inspect parts to determine in which direction the spool is cocked. A few very light taps with a plastic hammer should align and free the spool in the bore. Remove and discard "O" ring dampener seal from spool.
6. Carefully remove valve body Teflon rings and ring back-up "O" ring seals.

Fig. SR3 Removing end plug retaining ring

Fig. SR4 Installing rack-piston arbor tool in end of worm

Fig. SR5 Removing adjuster plug

Fig. SR6 Rotary valve parts

Disassemble Housing

1. Remove pitman shaft outer dust seal retaining ring.
2. Remove outer dust seal.
3. Remove seal (double lip) by inserting offset screwdriver between seal and back-up washer and prying out of housing.
4. Remove back-up washer.
5. Remove seal (single lip) by cutting and collapsing seal.
6. Remove pitman shaft needle bearings (if necessary) with a suitable driver.
7. If connectors are to be removed, tap threads in holes of connectors using 5/16-18 NF tap. Remove connectors by using threaded bolt into tapped holes with washer and nut as extractor.

ASSEMBLE SUB-ASSEMBLIES

Refer to Fig. SR2 and lubricate all parts as they are assembled.

1. Screw lash adjuster through side cover until cover bottoms on pitman shaft gear. Install lash adjuster lock nut while holding lash adjuster with 7/32" allen wrench.
2. Mount adjuster plug in vise with soft jaws.
3. If it has been removed, assemble needle bearing by pressing towards thrust bearing end of adjuster plug against identification end of bearing. End of bearing to be flush with bottom surface of stub shaft seal bore.
4. Install stub shaft far enough to provide clearance for dust seal and retaining ring. Install new dust seal with rubber surface outward. Install new retaining ring.
5. Assemble large thrust bearing race, thrust bearing, small race and spacer (with grooves up) on adjuster plug, Fig. SR7, and secure with retainer.

Assembly Rotary Valve

1. Assemble one valve body Teflon ring back-up "O" ring seal in each groove in valve body, being sure seals do not become twisted.
2. Assemble valve Teflon rings in ring grooves over "O" ring seals by carefully slipping rings over valve body. The rings may appear loose or twisted in the grooves but the heat of the oil during subsequent operation will cause them to straighten.
3. Install valve spool dampener "O" ring seal in valve spool groove, being sure it is not twisted.
4. Assemble stub shaft in valve body, aligning groove in valve cap with pin in valve body, Fig. SR8. Press on cap until it is against shoulder in valve body with body pin in cap groove. Hold these parts together during rest of assembly.
5. With notch end of spool towards valve body, install spool, aligning spool notch with pin in stub shaft.
6. Slide spool spring over stub shaft and work spring into position.

Fig. SR7 Adjuster plug parts

7. Lubricate cap-to-worm "O" ring and install in valve body. *During assembly of the valve, if the stub shaft and cap is allowed to slip out of engagement with the valve body pin, the spool will be permitted to enter the valve body too far. The dampener "O" ring seal may expand into valve body oil grooves, preventing removal of spool.* If this happens, remove spool spring and disassemble rotary valve. Press on spool until "O" ring seal is cut and can be removed. Install new "O" ring and reassemble.

Assemble Housing

1. With stamped end of needle bearing facing outward, drive bearing into bore from outside of housing until flush to $\frac{1}{32}$" below shoulder. Make sure bearings rotate freely.
2. Lubricate cavity between lips of pitman shaft (double lip) seal with high melting point, water resistant wheel bearing lubricant.
3. Lubricate and install pitman shaft seals as shown in Fig. SR8. Make sure seal lips are properly positioned, retaining ring is seated, and that approximately $\frac{1}{16}$" clearance is maintained between the inner (single lip) seal and bearing.
4. If connectors were removed, install new ones by driving them into place.

Assemble Rack-Piston and Worm

1. Lubricate and install new ring back-up seal and Teflon piston ring on rack-piston nut, being careful ring and seal do not twist during installation.
2. Insert worm into rack-piston nut to bearing shoulder, Fig. SR9.
3. Align ball return guide holes with worm groove. Load 16 balls into guide hole nearest the Teflon piston ring while slowly rotating worm to left to feed balls through circuit. If balls are installed properly the worm should turn out of rack-piston nut.
4. Fill one-half of ball return guide with remaining six balls. Place other guide over balls and plug each end with heavy grease to prevent balls from falling out when installing guides into rack-piston nut.
5. Insert guides into guide holes of rack-piston nut. Guides should fit loosely.

Check Worm Preload

The worm groove is ground with a high point in the center. When the rack-piston nut passes over this high point, a preload of a ½ to 5 inch pounds torque should be obtained.

1. With worm pointing up, clamp rack-piston nut in a vise with soft jaws (do not hold rack-piston nut in area of Teflon ring).
2. Place valve on worm, engaging worm drive pin.
3. Rotate worm until it extends 1¼" from rack-piston nut to thrust bearing face, Fig. SR10. This is the center position.
4. Attach an inch pound torque wrench with socket on stub shaft, Fig. SR10. Oscillate wrench through a total arc of approximately 60° in both directions several times and take a reading. The highest reading obtained with worm rotating should be between ½ and 5 inch pounds. Take a torque reading pulling the torque wrench to the right and a reading pulling the wrench to the left. Total both readings and take one-half of this total as the average torque. *Do not use a torque wrench having maximum torque reading of more than 100 inch pounds.*

Refitting Rack-Piston Balls

Do not refit balls unless the steering is loose. If such is the case, a thrust adjustment and over-center adjustment should correct the problem if it lies in the steering gear. If balls are pitted or rough, then select the proper ball size for proper adjustment.

If the torque reading obtained above is too high or too low (on new balls only), disassemble and reassemble, using the next size smaller (or larger) balls and recheck worm preload.

A rack-piston nut with a ball size of 7 does not have a number stamped on the flat surface. For ball sizes other than 7, the ball size is stamped on the flat surface of the rack-piston nut. Ball sizes are numbered from 6 to 11, with 6 being the smallest and 11 the largest. Ball sizes are graduated in increments of .00008" from .28117" to .28157".

STEERING GEAR, ASSEMBLE

Install Rack-Piston Worm and Valve

1. Install valve and worm in housing as a unit, Fig. SR13.
2. Install new "O" rings on adjuster plug.
3. Install adjuster plug on stub shaft in gear housing finger tight.
4. Slip stub shaft flange on end of stub shaft.
5. Holding a suitable Teflon ring compressor sleeve tightly against shoulder of gear housing, insert rack-piston nut and arbor into housing, holding arbor until it contacts worm end.
6. Holding arbor tight against worm, turn stub shaft flange and worm to draw ball nut onto worm and into housing until arbor is free. Be certain that no balls drop out.
7. Remove arbor and sleeve.

Fig. SR8 Pitman shaft seals and washers

Install Rack-Piston Nut End Plug

1. Install new "O" ring seal on end plug, being careful not to allow seal to twist in groove.
2. Install end plug in rack-piston nut by pressing into place.
3. Install end plug retaining ring, being sure ring is bottomed in its groove.

Install Housing Lower End Plug

1. Install new housing end plug "O" ring seal.
2. Insert end plug into gear housing and seat against "O" ring. Slight pressure may be necessary to seat end plug properly.
3. Install end plug retainer ring so end of ring extends over and at least ½" beyond ring removal assist hole.

Thrust Bearing Preload, Adjust

1. Position rack-piston nut in housing to end of travel, back off ¼ turn and remove stub shaft flange.
2. Tighten adjuster plug snug and back it off ⅛ turn.
3. Center the worm and adjust thrust bearing so that *preload is 3 to 4 inch pounds in excess of worm and rack-piston nut preload, when holding rack-piston from turning and swinging torque wrench back and forth through a 60° arc.*
4. Install adjuster plug lock nut and tighten to 50 ft. lb. torque.

Fig. SR9 Loading rack-piston nut

Fig. SR10 Checking worm preload

Fig. SR11 Worm shaft and rotary valve parts

Fig. SR12 Adjusting pinion shaft preload

5. Recheck thrust bearing preload. Total thrust bearing adjustment plus seal drag not to exceed 10 inch pounds torque.

Install Pitman Shaft Gear and Side Cover

1. Install stub shaft flange and turn steering worm until center groove of rack-piston is aligned with center of pitman shaft needle bearings.
2. Install new side cover "O" ring.
3. Install pitman shaft gear so that center tooth of gear meshes with center groove of rack-piston. Make sure side cover "O" ring is in place before pushing cover against housing.
4. Install and torque side cover screws to 25-30 ft. lbs. torque.

Adjust Pitman Shaft Preload Through Center High Point

After steering gear is assembled, find center or straight-ahead position of worm by rotating worm through full travel, counting the number of turns and reversing one-half the number of turns counted.

Using a suitable socket and inch pound torque wrench as shown in Fig. SR12, adjust lash adjuster so torque is between 4 and 8 inch pounds in excess of total preload (after recording of adjuster nut preload) when swinging torque wrench back and forth through a 20° arc.

Total over center preload must not exceed 18 inch pounds through center high point when rotating worm shaft through an arc of 20°. Tighten lash adjuster nut to a torque of 25-30 ft lbs. Recheck preload after nut has been tightened.

Install Stub Shaft Flange

Rotate stub shaft slightly over two complete turns from either extreme right or left turn. This will place gear in center position, which will place torsion bar pin through stub shaft in a straight up and down position.

Rotate flange so the bolt with the large head is in top position. Visually align the block tooth in the serrations of the flange with the torsion bar pin and install flange on stub shaft. Tighten flange clamping bolt to a torque of 25-30 ft. lbs.

SUB-ASSEMBLIES, INSTALL

1. Position gear housing in vise with adjuster plug end facing up.
2. Lubricate worm shaft, lower thrust bearing and races with power steering fluid, then position thrust bearing and races on worm.
3. Align valve body drive pin on worm with narrow pin slot on valve body. Be sure O-ring seal between valve body and worm head is installed.
4. Position valve body and worm shaft in housing as a unit. *CAUTION—Do not push against stub shaft as this might cause stub shaft and cap to pull out of valve body, allowing spool seal to slip into valve body oil grooves. Valve assembly can be installed by pushing on outer diameter of valve body housing with the fingers of both hands. Make certain that Teflon rings are not binding on inside of housing. Valve is properly seated when oil return hole in gear housing is fully visible.*

Fig. SR13 Installing adjuster plug

Fig. SR14 Installing rack-piston seal compressor

5. Place a suitable seal protector over end of stub shaft, Fig. SR13.
6. Lubricate new adjuster plug O-ring seal with power steering fluid and install in groove on adjuster plug.
7. Install adjuster plug over end of stub shaft and tighten just enough to make certain that all parts are properly seated in gear housing. Remove seal protector.
8. Install adjuster plug lock nut loosely on adjuster plug.
9. Install seal compressor in gear housing, holding it tightly against shoulder in housing, Fig. SR14.
10. Insert rack-piston into housing until arbor engages worm. Turn stub shaft clockwise, using a ¾" wrench, to draw rack-piston into housing. When piston ring is in housing bore, arbor and seal compressor can be removed.
11. Turn stub shaft as necessary until middle rack groove in rack-piston is aligned with center of pitman shaft needle bearing.
12. Lubricate new side cover O-ring seal and install in groove in face of side cover.
13. Assemble side cover on pitman shaft by screwing cover onto adjusting screw until cover bottoms

Fig. SR15 Adjusting thrust bearing preload

on pitman shaft.

14. Install pitman shaft so that center tooth in sector meshes with center groove of rack-piston. Make sure side cover O-ring is in place before pushing side cover down on gear housing.
15. Install side cover screws and lock-washers and tighten to 30 ft-lbs.
16. Hold adjuster screw with Allen wrench and install new adjuster lock nut halfway on adjuster screw.
17. Install rack-piston end plug in rack-piston and tighten plug to 50 ft-lbs.
18. Lubricate new housing end plug O-ring seal with power steering fluid and install in gear housing.
19. Insert end plug into gear housing and seat against O-ring seal. Slight tapping with a mallet may be necessary to seat end plug properly.
20. Snap end plug retainer ring into place with fingers. Slight tapping may be required to bottom ring in housing securely.
21. Position gear assembly with stub shaft end up and adjust thrust bearing preload as follows:
    a. Using spanner wrench, lightly tighten adjuster plug and then back off ⅛ turn, Fig. SR15.
    b. Install O-25 inch-lb torque wrench as shown with a ¾", 12 point socket on stub shaft splines.
    c. Rotate stub shaft to either left or right turn stop and then back off from stop ½ turn.
    d. Rotate torque wrench in a 45 degree arc and note highest reading.
    e. Tighten adjuster plug with spanner wrench until there is a preload of 1-3 inch-lbs higher than initial load reading just measured.
    f. Tighten adjuster plug lock nut securely with punch and hammer.
    g. Recheck preload to be sure it still reads 1-3 inch-lbs higher than initial load. If adjustment has changed, readjust.
22. Adjust pitman shaft end play as follows:
    a. Rotate stub shaft from one stop to the other and locate center of travel.
    b. With gear on center, check combined ball and thrust bearing preload with torque wrench with a ¾", 12 point socket and note highest reading, Fig. SR16.
    c. With pitman gear on center and adjuster screw lock nut backed off, adjust pitman shaft so that preload is 8-10 inch-lbs in excess of total preload and drag.

    NOTE—These readings must be made by rotating torque wrench in a 20 degree arc. Total preload of gear should not exceed 20-inch-lbs.

    d. With gear on center and reading achieved, tighten adjuster screw lock nut to 30 ft-lbs.
23. Install coupling flange on stub shaft and install flange screw in coupling. Tighten screw to 30 ft-lbs.

Fig. SR16 Adjusting pitman shaft end play

TROUBLE SHOOTING

Hard Steering

1. Frozen steering shaft bearings.
2. Lower coupling flange rubbing against adjuster.
3. Steering adjustment tight.

Poor Return of Steering

1. Frozen steering shaft bearings.
2. Lower coupling flange rubbing against adjuster.
3. Tires not inflated properly.
4. Incorrect caster and toe-in.
5. Tight steering linkage.
6. Steering gear misalignment.
7. Tight suspension ball joints.
8. Steering adjustment tight.
9. Thrust bearing adjustment tight.
10. Tight sector-to-rack piston adjustment.
11. Rack piston nut and worm preload too tight.
12. Sticky valve spool.

Car Leads to One Side

1. Front end misalignment.
2. Unbalanced or badly worn valve.

Momentary Increase In Effort When Turning Wheel Fast

1. Low oil level in pump.
2. Pump belt slipping.
3. High internal leakage.

External Oil Leaks

1. Loose hose connections.
2. Damaged hose.
3. Side cover O-ring seal.
4. Pitman shaft seals.
5. Housing end plug seal.
6. Adjuster plug seals.
7. Torsion bar seal.

Steering Gear Noise

1. A rattle or chuckle noise caused by loose over-center adjustment.
2. A hissing sound caused by gear being loose on frame.

Excessive Wheel Kickback or Loose Steering

1. Lash in steering linkage.
2. Air in system.
3. Excessive lash between pitman shaft sector and rack piston.
4. Loose thrust bearing adjustment.
5. Ball nut and worm preload.

Wheel Surges or Jerks

1. Loose pump belt.

Hard Steering When Parking

1. Loose pump belt.
2. Low oil level in reservoir.
3. Lack of lubrication in linkage or front suspension.
4. Tires not properly inflated.
5. Insufficient oil pressure.
6. Low oil pressure due to restriction in hoses.
7. Low oil pressure due to worn piston ring or scored housing bore.
8. Pressure loss due to leakage at valve rings, valve body-to-worm seal or rack piston end plug seal.
9. Pressure loss due to loose fit of spool in valve body or leaky valve body.

Valve Squawk

1. Cut or worn dampener ring on valve spool.
2. Loose or worn rotary valve parts.

No Effort Required to Turn

1. Broken torsion bar.

REAR AXLE SERVICE

TROUBLE DIAGNOSIS

External Noises

When a rear axle is suspected of being noisy, it is advisable to make a thorough test to determine whether the noise originates in the tires, road surface, front wheel bearings, engine, transmission, or rear axle assembly. Noise that originates in other places cannot be corrected by adjustment or replacement of parts in the rear axle assembly.

Road Noise

Some road surfaces, such as brick or rough surfaced concrete, cause noise that may be mistaken for tire or rear axle noise. Driving on a different type of road, such as smooth asphalt or dirt, will quickly show whether the road surface is the cause of noise. Road noise usually is the same on drive or coast.

Tire Noise

Tire noise may easily be mistaken for rear axle noise even though the noisy tires may be located on the front wheels. Tires worn unevenly or having surfaces of non-skid divisions worn in saw-tooth fashion are usually noisy, and may produce vibrations that seem to originate elsewhere in the vehicle. This is particularly true with low tire pressure. Some designs of non-skid treads may be more noisy than others, even when tires are new.

Test for Tire Noise

Tire noise changes with different road surfaces, but rear axle noise does not. Temporarily inflating all tires to approximately 50 pounds pressure, *for test purposes only,* will materially alter noise caused by tires, but will not affect noise caused by rear axle. Rear axle noise usually ceases when coasting at speeds under 30 mph; however, tire noise continues but with lower tone as car speed is reduced. Rear axle noise usually changes when comparing "pull" and "coast" but tire noise remains about the same.

Front Wheel Bearing Noise

Loose or rough front wheel bearings will cause noise that may be confused with rear axle noises; however, front wheel bearing noise does not change when comparing "pull" and "coast". Light application of brake while holding car speed steadily will often cause wheel bearing noise to diminish as this takes some weight off the bearings. Front wheel bearings may be easily checked for noise by jacking up the wheels and spinning them, also by shaking them to determine if bearings are loose.

Engine & Transmission Noises

Sometimes a noise that seems to originate in the rear axle is caused by the engine or transmission. To determine which unit is actually causing the noise, observe approximate car speeds and conditions under which the noise is most pronounced; then stop the car in a quiet place to avoid interfering noises. With transmission in neutral, run engine slowly up and down through engine speeds corresponding to car speed at which the noise was most pronounced. If a similar noise is produced with car standing, it is caused by the engine or transmission, and not the rear axle.

Rear Axle Noises

If a careful test shows that noise is not caused by external items described above, it is then reasonable to assume that noise is caused by the rear axle assembly. The rear axle should be tested on a smooth level road to avoid road noise. It is not advisable to test rear axle for noise by running with rear wheels jacked up.

Noises in the rear axle assembly may be caused by a faulty propeller shaft, faulty rear wheel bearings, faulty differential or pinion shaft bearings, misalignment between two universal joints, or worn differential side gears and pinions. Noises may also be caused by mismatched, improperly adjusted or scored ring and pinion gear sets.

Rear Wheel Bearing Noise

A rough rear wheel bearing produces a vibration or growl that continues with car coasting and transmission in neutral. A brinelled rear wheel bearing causes a knock or click approximately every two revolutions of the rear wheel, since the bearing rollers do not travel at the same speed as the rear axle or wheel. With rear wheels jacked up, spin rear wheels *by hand* while listening at the hubs for evidence of rough or brinelled wheel bearing.

Differential Side Gear & Pinion Noise

Differential side gears and pinions seldom cause noise since their movement is relatively slight on straight ahead driving. Noise produced by these gears will be most pronounced on turns.

Pinion Bearing Noise

Rough or brinelled pinion bearings produce a continuous low pitch whirring or scraping noise starting at relatively low speed.

Ring & Pinion Gear Noise

Noise produced by the ring and pinion gear set generally shows up as drive noise, coast noise, or float noise.

1. Drive noise is produced during vehicle acceleration.
2. Coast noise is noise produced while allowing car to coast with throttle closed.
3. Float noise is noise occurring while just maintaining constant car speed at light throttle on a level road.

Drive, coast and float noises will vary in tone with speed, and will be very rough and irregular if the differential or pinion shaft bearings are rough, worn or loose.

Body Boom Noise or Vibration

Such objectionable noises at 55-65 mph can be caused by an unbalanced propeller shaft. Excessive looseness at the spline can contribute to this unbalance. Other items that may also contribute to noise problem are:

1. Undercoating or mud on the propeller shaft causing unbalance.
2. Shaft balance weights missing (if equipped).
3. Shaft damage such as bending, dents or nicks.
4. Tire-type roughness. Switch tires from a known good car to determine tire fault.

Check for Propeller Shaft Vibration

Objectionable vibrations at high speed (65 mph or higher) may be caused by a propeller shaft that is out of balance. Out of balance may be due to a bent shaft.

To determine whether propeller shaft is causing vibration, drive car through speed range and note speed at which vibration is most pronounced. Shift transmission into a lower gear and drive car at same speed as when vibration was most pronounced in direct drive. Note effect on vibration.

If the vibration is still present at the same engine speed whether in direct drive or in a lower gear, since the propeller shaft speed varies, this cannot be the fault. If the vibration decreases or is eliminated in the lower gear, then the propeller shaft is out of balance and should be rebalanced.

Oil Leaks

1. Oil coming from the drain hole under axle housing at the brake backing plate is caused by a leaking axle shaft seal or a leaking wheel bearing inner gasket.
2. Oil coming from between rear pinion flange slinger and carrier is caused by a leaking pinion seal.
3. Even after a point of leakage has been determined, it is difficult to tell whether the oil is leaking past the lip of the seal or past the outside diameter of the seal. Therefore, it is a good idea to make sure the leak is stopped by using a non-hardening sealing compound around the outside diameter of the seal.

General Instructions

In rear axle service work, there are minor and major operations. Minor operations, such as the removal of axle shafts, bearings and oil seals, can be performed in most cases without removing the differential carrier from the axle housing. (For detailed instructions covering the removal, installation and adjustment of axle shafts, bearings and oil seals, see the car chapters.)

Major operations, such as the replacement of ring gear and pinion, must be performed with the differential carrier removed from the axle housing. The preliminary work required to remove the differential carrier depends upon the construction employed. In some cases, a removable cover is attched to the back of the axle housing, while in others it is welded to the housing. (Procedure for removing differential carriers and axle

Fig. 1 Marking differential adjusting nuts and bearing caps before dismantling the assembly

assemblies is given in the car chapters.)

Disassembly

Before dismantling the carrier, bear in mind that the factory adjustment of ring gear and pinion sets should not be disturbed unless absolutely necessary. For example, should it become necessary to tear down a differential to replace some part other than a ring gear and pinion, do not disturb the drive pinion adjustment in either disassembling or assembling the unit—assuming of course that is was correct beforehand. Instead, only adjust the ring gear when assembling the unit—which will increase the chances of securing a setting precisely the same as the original setting. In addition, backlash between the ring gear and pinion should be checked and noted before dismantling the unit in order that the gear may be adjusted to the original backlash when making the final adjustments.

It should be remembered that ring gears and pinions are matched at the factory and should remain matched in service. Many times, when one member of a ring gear and pinion set is divorced from the other, the new combination results in a certain amount of noise and an abnormal amount of wear and strain on the teeth. Because of this, service replacements are furnished in matched sets.

With the differential carrier mounted in a vise or fixture, the next step consists of removing the ring gear and differential from the carrier. Before proceeding, however, scratch a mark on each differential adjusting nut and bearing cap, Fig. 1. These marks not only locate on which side of the carrier the adjusting nuts and bearing caps are mounted but they show the number of threads exposed on each adjusting nut, and the exact position of the nuts with relation to the bearing caps. If the same ring gear and pinion are to be used again, these marks will serve to bring the original adjustment into being with a minimum of time and effort. (If the differential bearings are adjusted by shims, Fig. 2, simply tie each set of shims together and carefully lay them aside until needed).

Fig. 2 Differential carrier of the type having shims for adjusting differential bearings

After removing the differential bearing cap screws, take off the caps and adjusting nuts and lift the differential out of the carrier. Where shims are used for adjusting differential bearings, remove the caps from the bearings and pry the differential out of the carrier. Figs. 3 and 4.

The first step in the disassembly of the differential is to remove the ring gear. After removing the attaching cap screws, drive the gear off the differential case by tapping lightly with a soft-faced hammer or mallet. Drive out the differential pinion shaft lock pin, Fig. 5, and push out the shaft (sometimes a lock screw is used). The side gears, pinions, thrust washers, thrust block (if used) and spacers will then be loose and may be picked out of the differential case, Fig. 6. The differential bearings may then be removed from the case with a suitable puller.

The next step is to disassemble the drive pinion. However, it should be removed and disassembled only when it is necessary to replace a part, or to examine closely all parts in connection with a major inspection and overhaul operation.

In this connection, however, if the differential carrier was satisfactory from the standpoint of noise before being taken apart, or if it is disassembled for the replacement of a part other than a ring gear and pinion, the location and quantity of shims should be noted. The shims then should be cleaned, tagged and tied together and carefully hung on a hook or set to one side so that, upon re-

Fig. 3 Prying differential from carrier on type having shim adjusted bearings. If spreader tool shown is not available, pry out differential as shown in Fig. 4

Fig. 4 Using two pry bars to remove differential from carrier on type having shim-adjusted bearings

Fig. 5 Removing differential pinion shaft lock pin

assembly, the original setting may be obtained without delay.

When removing and replacing pinion oil seals, care should be taken to avoid cutting the seal on the sharp edges of the pinion shaft threads, keyway or splines. If the seal is cut and is not replaced, serious leakage of lubricant is almost certain to result.

The best way to guard against cutting the seal is to wrap a piece of shim stock around the pinion shaft so that the oil seal will not come in contact with any sharp edges when the seal is slid off and on. Be sure to blunt or dull the edges of the shim stock so it will not cut the seal.

Inspection

Bearings

Before inspecting bearings, each one should be cleaned by swishing it around in a pail of clean gasoline or kerosene until it is entirely free from grease and oil. Then blow dry with compressed air (if available) rotating the bearing slowly by hand—not by the air pressure. When cleaned and dried, lubricate the bearing with clean engine oil, rotate it by hand, and check for wear and rough spots. If any defects are discovered, it should be discarded.

Score marks on the contact face of gear teeth show up as light colored areas which are caused by instantaneous fusing of the mating gear teeth, and usually run from the bottom to the top of the tooth.

A scoring condition may be the result of insufficient lubrication, the improper lubricant for the load required for the gears, dirty lubricant, or improper tooth contact. The gears in the differential which usually cause noisy operation from these conditions are the ring gear and pinion. The side gears and differential pinions rarely give trouble. In fact, they can be badly worn without affecting the operation of the differential, as they are used only when one rear wheel travels faster than the opposite rear wheel. In spite of this, however, worn side gears and differential pinions should always be replaced during an overhaul operation. If not, the condition will become worse and eventually, through failure of these parts, another tear-down will be required.

Fig. 7 Checking ring gear mounting flange for run-out

Assembly

The sequence of operations in assembling any piece of mechanism is usually performed in the reverse order from which it was disassembled. Differential carrier units are no exception although the sequence given below may be changed to suit shop conditions. For example, instead of starting with the differential case and ring gear, the drive pinion may be set up and adjusted in the carrier first.

Checking Diff. Case Runout

Mount the differential case on V blocks, Fig. 7, and check the run-out of the ring gear pilot and case flange. To make this check, mount the dial indicator as shown, with the indicator needle set to zero and the contacting pin just touching the surface to be checked.

Rotate the differential case in the V blocks for one complete revolution and note the amount of deflection on the needle. If the deflection is in excess of the maximum allowable run-out (usually .002 inch) replace the differential case or true it up on a lathe.

Differential Parts

All parts of the differential, including gears, differential case, carrier, and the axle housing, should be washed thoroughly in clean gasoline or kerosene. Particular attention should be given to remote corners and recesses in the carrier and axle housing to be sure that all muck, grit, gear chips and old grease are removed.

Examine the ring gear and pinion for cracked, chipped or scored teeth. Inspect the bearing surfaces, also the side gears and differential pinion surfaces of the differential case for evidence of roughness or scoring. Inspect the thrust faces of the differential pinions and check their fit on the pinion shaft. Inspect the thrust surfaces of the side gears and check their fit on the axle shafts. Any gears showing any of the above conditions should be scrapped. If the case is equipped with side gear and pinion gear thrust washers, inspect the washers and replace if worn.

Ring Gear, Install

If the ring gear is the bolt-on type, cut the heads from five or six 1½ inch cap screws having the same thread as the ring gear cap screws. (These are to be used as guide pins and can be kept for future jobs.) Cut screwdriver slots in the end of these guide pins and screw them in every other hole in the ring gear. Be sure the back face of the ring gear and differential flange face are clean and free from nicks and burrs, and any rust preventive film that may be present.

Slip the ring gear with the guide pins on the differential case and tap it in place

Fig. 6 Layout of differential parts (typical)

with a mallet. Install the regular cap screws in the open holes and draw them up evenly and tightly. Remove the guide pins and install the other cap screws. New lock washers should be used and if the cap screw heads are drilled, use new wire to lock them in place.

Mount the assembly in V blocks, Fig. 8, and check the run-out of the back face of the ring gear in the same manner as described above for the differential case. If the deflection of the needle is in excess of the maximum allowable run-out (usually .006 inch) the ring gear may not be bolted evenly against the flange face. Sometimes this check is made with the side bearings mounted on the differential case hubs. If so, and the run-out is excessive, the bearings may be mounted incorrectly or they may be cocked on the hubs.

If the ring gear is riveted on the case, it should be removed and replaced in the following manner: Drill through the head of each rivet, using a drill slightly larger than the hole in the case. When the drill penetrates through the case, the head will come off and the rivet can then be driven out. Always drill rivets from the differential case flange side. Do not cut them off with a chisel as this distorts the case, Fig. 9. Remove any burrs from around the rivet holes, and check the run-out of the case as described above.

Fig. 8 Checking back face of ring gear for run-out

Fig. 9 Removing ring gear rivets

Assembly Of Differential

When installing the differential gears and thrust washers (if used), coat these parts with differential lubricant to facilitate holding them in place while replacing the differential pinion shaft.

Slip the side gear thrust washers and side gears in the differential case. Roll the differential pinions in place, rotating the side gears until the hole through the center of the pinions is in line with the hole for the pinion shaft in the case. Install the axle shaft thrust block (if used) and push the pinion shaft in place so that the hole in the shaft for the lock pin or screw registers with the hole in the case. Install the lock pin and peen over the outside edge of the hole to prevent the pin from coming loose in service. If a lock screw is used, install a new lock washer and set the screw up tight.

Fig. 10 Example of pinion depth markings

Fig. 11 Effect of shim pack thickness on pinion position

Fig. 12 Showing gear movement and tooth terminology

Before riveting on the new gear, bolt it to the case through every other hole and draw down tight to prevent the rivets being squeezed out between the ring gear and the case. Use cold rivets and a riveting machine, if possible and always head the rivets on the ring gear flange—never on the back of the differential case.

The use of hot rivets, headed over by hand, is only recommended as a last resort when cold riveting equipment is not available. This is because when hot rivets cool off, they contract and very often are loose in the holes, with the result that when the gear is under load, the rivets shear off.

Head over one rivet, turn the differential case halfway around and head a rivet at this point. Then head over a rivet between the two already installed, working successively from one side of the gear to the other until all open holes are filled. Remove the temporary bolts and install the rivets in these holes in the same manner.

When the job is completed, mount the assembly in V blocks and check the runout on the back face of the gear in the manner described above. If excessive, the ring gear may not be riveted evenly against the flange face. If this is the case, remove the rivets and make the installation correctly.

Differential Bearings, Install

Install the differential side bearings, with the thick side of the inner races toward the case. Be sure they are not cocked and that the inner races seat squarely against the hubs of the differential case. This completes the assembly of the differential unit.

Drive Pinion, Install

Due to the fact that all gears are not made on the same machine, a definite setting for pinion depth in the carrier to bring the ring gear and pinion exactly on the same cone centers is determined in manufacture by testing each ring gear and pinion set. These setting marks are usually etched on the toe end of the pinion and read "O", or plus (+) or minus (—) a nominal amount in thousandths of an inch. Fig. 10 is an example showing a pinion marked plus .002" (+2) and another marked minus .002" (+2).

A plus mark indicates that the pinion must be moved outward (shims added); a minus mark indicates that the pinion must be moved inward (shims removed), Fig. 11. Fig. 12 explains gear movements and tooth terminology.

In order to make these depth settings in accordance with the marks on the pinion, a pinion setting gauge is helpful. There are several of these gauges commercially available, each differing in detail but not in principle. Measurements are taken either by a micrometer or by a dial gauge.

As shown in Figs. 13 and 14, these gauges are provided with a measuring rod for setting the pinion, and are made adjustable to accommodate all width differential carriers. Manufacturers of these gauges usually provide complete instructions for their use, and data giving the nominal dimension for the various model pinions on which the gauge can be used.

NOTE: If a pinion setting gauge is not available, a satisfactory job can be done by referring to the *Rear Axle Specifications* tables in the car chapters and then proceed as follows:

1. Measure the thickness of the original pinion depth shim removed from the rear axle.
2. Use the same thickness shim upon installation of the new pinion. If any further shim change is necessary, it will be indicated in a tooth pattern check as described further on.

Fig. 13 Micrometer type pinion setting gauge

3. If the original shim is lost, substitute a nominal shim for the original and use the tooth pattern check to determine if further shim changes are required.

Install the pinion in the carrier, using the shims from the old pinion. Then check the pinion shaft end play and make necessary corrections. Two methods are used to establish the preload: by shims behind the front bearing, or by a collapsible spacer between the front and rear bearings.

Shim Adjusted Bearing Preload

To check the end play, place a dial indicator on the outer end of the pinion, Fig. 15. Work the pinion in and out and note the amount of end play indicated on the gauge. If the job calls for a preload of .002", for example, and the indicated end play is .004", .006" inch of shimming should be removed to give the required preload of .004".

Collapsible Spacer Preload Adjustment

Fig. 16 shows the method of setting the preload when the specification calls for the adjustment in inch-pounds; Fig. 17 shows the spring scale method when the specification calls for pounds pull adjustment.

To adjust the preload, draw up the pinion flange nut until the spacer starts to buckle. Check the pull with the torque wrench or the spring scale.

This adjustment must be made every time the flange nut is removed or loosened. If the adjustment is made with the differential unit in the carrier, the rear wheels must be jacked off the floor.

Fig. 15 Checking end play of drive pinion

NOTE: A new spacer is required when a new ring gear and pinion set is installed, when one or both pinion bearings is changed, when a new carrier casting is used, or when the pinion depth adjusting shim thickness is increased.

When the same pinion flange is removed and reinstalled, as when an oil seal is replaced, checking the pinion bearing preload is not necessary if care is taken to tighten the flange nut exactly to its previous position. Should a new pinion flange be required, a torque wrench or spring scale reading (whichever is specified) should be taken before loosening the nut, and the nut tightened the same amount when the installation is made.

Rear Axle Adjustments

Four adjustments can be made which will affect tooth contact pattern: side bearing preload, drive pinion bearing preload, ring gear and pinion backlash, and position of drive pinion in carrier. The effect of bearing preloads are not readily apparent on (hand loaded) red lead tests; however, these adjustments should be within specifications before proceeding with backlash and drive pinion adjustments.

Backlash is adjusted by means of side bearing adjusting nuts or shims which move the entire case and ring gear assembly closer to or farther away from the drive pinion. The adjusting nuts or shims are also used to set the side bearing preload.

The position of the drive pinion is adjusted by increasing or decreasing the shim pack between the pinion head and the inner race of the rear bearing. The shim pack is used in the differential to compensate for manufacturing tolerances. Increasing shim pack thickness will move the pinion closer to the centerline of the ring gear, Fig. 18. Decreasing shim pack thickness will move pinion farther away from center line of ring gear.

Differential Bearing Preload

Upon completion of the pinion setting operation, assemble the differential unit in the carrier and proceed as follows:

If the same ring gear and pinion are being used again, and if the adjustment was correct before the unit was dismantled, adjust the bearings according to the marks, Fig. 1, that were scratched on the bearing caps and adjusting nuts. If the differential bearings are adjusted by shims, assemble the unit with the same quantity of shims used originally.

If a new ring gear and pinion are being used, or if an adjustment of the old gears was necessary, proceed as follows, being sure to leave off the drive pinion bearing oil seal to eliminate any drag from this source when making adjustments.

To make the adjustment on units having adjusting nuts, place the differential in the carrier and install the adjusting nuts, taking care to slide these nuts alongside the bearings so that the threads on the nuts fit properly into the threads of the carrier. Install the bearing caps, being sure the marks on the caps line up with the marks on the carrier.

Fig. 14 Dial indicator type of pinion setting gauge

Start the cap screws and drop the bearing caps on the adjusting nuts, using the screws as a pilot so as not to cross the threads. Tighten the cap screws and then loosen them from 1 to 1½ turns.

Loosen the right adjusting nut until the ring gear and differential case are loose in the bearings—usually four to five notches. Tighten the left-hand nut against the bearing race, removing all backlash between the ring gear and pinion, then back off three or four notches.

Tighten the right-hand nut until the bearing race starts to turn—indicating tension on the bearing. Continue to tighten one to two notches more, then back off the nut until the bearing race stops turning. Retighten this same nut until the bearing race again starts to turn, continuing for two notches more and whatever further tightening is necessary to bring the slot in the nut in line with the bearing cap lock, Fig. 19. Tighten the bearing cap screws and check the ring gear and pinion backlash.

Backlash, Adjust

To check the backlash, mount a dial indicator on the carrier, Fig. 19. To assure an accurate reading, make sure the dial indicator is square with the face of the gear tooth it contacts, and that the pointer is set to zero.

CAUTION—When making this or any other adjustment of the ring gear, tighten the cap screws of the differen-

Fig. 16 Using torque wrench to adjust pinion bearing preload

Fig. 17 Using spring scale to adjust pinion bearing preload

tial bearing caps after each adjustment has been made. This will avoid "creeping" of the ring gear in any direction during the process. However, do not lock the cap screws or adjusting nuts until all adjustments have been completed.

Check the backlash by rocking the ring gear back and forth and noting the amount indicated on the gauge. If the backlash is not within the limits specified by the car manufacturer, an adjustment is required. If the backlash is greater than the allowable maximum, loosen the right-hand nut one notch and tighten the left-hand nut one notch. If the lash is less than the allowable minimum, loosen the left-hand nut one notch and tighten the right-hand nut one notch.

When the adjustment is correct, tighten the bearing caps securely, then recheck the backlash. Install the adjustment nut locks. If the cap screw heads are drilled, lock them with new wire. If nut locks are employed, Fig. 19, be sure to set the ears against the sides of the cap screw heads. Use new lock washers if this locking method is used.

If the differential bearings are adjusted by shims, the adjustment is obtained by the shims located at each side of the case between the shoulder of the case and the inner race of the bearing. These shims also establish the ring gear position with the pinion. Therefore, backlash must be checked whenever a bearing adjustment is made.

The correct bearing adjustment is one which will provide a specified preload when the differential unit is assembled into the carrier. To make an adjustment, remove the bearing cones and shims, using a suitable puller. Reinstall the bearing cones without the shims and place the assembly in the housing with the bearing cups. Force the unit to one side and check the clearance between the bearing cup and differential case with feeler gauges, Fig. 20. When the clearance is determined, add sufficient number of shims to obtain the specified bearing preload.

Remove the differential bearings and install equal thicknesses of shims on each side and replace the bearings. Reinstall the differential unit in the housing. This operation is made easier by cocking the differential bearing cups slightly when the differential is placed in the housing and then tapping them lightly with a mallet, Fig. 21. During this operation, be sure the ring gear teeth mesh with the pinion teeth before tapping the bearings in place. After the cups are in position, install the bearing caps. The caps and the gasket surface of the housing are sometimes marked on one side with a horizontal numeral and on the other side with a vertical numeral. The position of the numerals should coincide when installing the bearing caps.

Tighten the bearing caps securely and if there is any backlash between the ring gear and pinion, check the back face of the ring gear for run-out, Fig. 22, in a manner already described. If the total indicator reading is in excess

Fig. 20 Measuring clearance between bearing cup and differential case on shim-adjusted differential bearings

of .003 inch, it indicates a sprung differential case or an improperly installed ring gear. In either case, the assembly must be taken apart and rechecked thoroughly.

Mount the backlash gauge indicator on the carrier, and start checking the backlash between the ring gear and pinion. In the event the lash is not within the proper limits it will be necessary to change the arrangement of the shims back of the bearings—which are supplied in thicknesses of .003, .005, .010 and .030 inch, any combination of which may be used to obtain the desired result. Make corrections in backlash, bearing in mind that shims removed from one side must be installed at the opposite side so that the total shim thickness of the right and left side will remain unchanged, and the bearing preload adjustment undisturbed.

NOTE—If a pinion setting gauge was not used to locate the pinion, tooth contact between the ring gear and pinion should be checked at this time, and in the following manner:

Fig. 18 Effects of shim pack thickness on pinion position

Fig. 19 Checking backlash between ring gear and pinion

Fig. 21 If spreader tool shown is not available, tap bearing cups lightly with a mallet to install differential unit

Fig. 22 Checking ring gear for run-out

Fig. 24 Contact too high and narrow. Move pinion toward center of axle

Fig. 25 Contact too low and narrow. Move pinion away from center of axle

Fig. 26 Short toe contact. Move ring gear away from pinion

Fig. 27 Short heel contact. Move ring gear toward pinion

Fig. 28 Correct tooth contact

Fig. 29 Measuring end play between axle shaft and thrust block

Gear Tooth Contact

Paint about 12 teeth of the ring gear, Fig. 23, with red lead of suitable consistency and use it sparingly. When the pinion is rotated, the paint is squeezed away by contact of the teeth, leaving bare areas showing the exact size, shape and location of the contacts. Sharper contact can be obtained by applying a small amount of resistance to the ring gear when rotating the pinion. This is done by holding a block of wood against the back of the ring gear, and using a wrench to rotate the pinion. By examining the contact marks, it can be determined whether contact is too high or too low, or too near the heel or toe.

If the contact is high and narrow, Fig. 24, remove shims so as to move the drive pinion in toward the toe of the gear teeth (toward the center of axle) to lower the contact area. This adjustment will decrease the backlash between the ring gear and pinion, which can be corrected by moving the gear away from the pinion. Several adjustments of both ring gear and pinion may be necessary before correct contact and backlash are secured, whether it is this one or those described below.

A low, narrow contact, Fig. 25, requires the addition of shims to move the pinion out from the gear (away from the center of the axle) a sufficient amount to move the contact area to the proper location. To obtain correct backlash, move the ring gear in toward the pinion.

Fig. 26 shows a short toe contact which is corrected by moving the ring gear away from the pinion. After establishing the correct contact, the proper backlash is obtained by moving the pinion in toward the toe of the ring gear teeth (toward center of axle).

Fig. 27 shows a short heel contact which is corrected by moving the ring gear in toward the pinion. Correct backlash is then obtained by moving the pinion out toward the heel of the ring gear teeth (away from center of axle).

When adjustments have been properly made, the contact shown in Fig. 28 will be secured. This adjustment provides a quiet operating gear set which, because the load is distributed over the teeth within the proper area, will provide normal service.

Tighten the bearing caps securely, then recheck the backlash. If correct,

install the adjusting nut locks, lock the adjustment and install the differential carrier unit in the axle housing, being sure the gasket is in good condition.

Some manufacturers provide thrust blocks of several thicknesses to maintain correct axle shaft end play. Where this construction is used, install the axle shafts and check the clearance as shown in Fig. 29. If the clearance does not come within the allowable limits, a new thrust block should be installed.

Lubrication

The differential carrier should be lubricated with the exact quantity, grade and type lubricant recommended by the manufacturer of the particular unit being serviced. The housing should never be filled above the level of the bottom of the filler plug hole.

Over-filling causes blown grease seals at the wheels, resulting in leakage and an accumulation of dirt and grease around the wheels, tires and brakes. On the other hand, if the lubricant is not kept up to the proper level, gears and bearings may run dry, resulting in excessive wear and noise.

SERVICE NOTE—All the foregoing is general information for servicing differential carrier units used on passenger cars included in this manual. To complete the picture, however, specific data such as specifications, drive pinion setups, special differential designs, propeller shaft installations on torque tube drive cars pertaining to each make of car are given in the car chapters.

LOCKING TYPE DIFFERENTIALS

The main purpose of these differentials is that they supply a greater percentage of torque to the wheel with better traction and still furnishes to the wheel with poorer traction as much torque as it is able to absorb under the circumstances.

In the conventional differential the wheel easiest to turn receives the power. Therefore, when traction conditions under the rear wheels are not the same, the driving force is limited by the wheel with the poorer traction (easiest to turn) even though one wheel is on good traction surface.

These locking differentials do not permit shock loads or full engine torque to be transmitted to one axle shaft. They provide power to both rear wheels and maintain the differential action that is necessary when the vehicle is turning a corner to permit the outer wheel to turn faster than the inner wheel.

Operational Test

To determine if the differential is functioning properly, place a roller-mounted floor jack far outboard under the rear axle housing and slightly raise one wheel off the floor. With one person guiding the jack, another can attempt to drive the car forward slowly. The unit is satisfactory if the car will move forward since the cones or clutches partially lock the rear axle enough to permit the car to move.

NOTE

"On car" type wheel balancers are not recommended for use on rear wheels of cars equipped with a locking differential. The rear wheel will drive if in contact with the ground or with a block even though the opposite wheel is raised. *However, this type of wheel balancer may be used by removing the wheel opposite of the one being balanced with the complete assembly raised. See additional "Service Note" at the end of this chapter.*

SPICER POWR-LOK

Differential Repairs

Before disassembling the differential, scribe a line across the differential case halves for alignment upon reassembly. Then, after removing the attaching bolts, separate the case halves and remove the differential parts.

Note the relative position of the friction plates, friction discs and Belleville spring plates (if used) so that they may be reassembled in the proper sequence, Figs. 1, 2 and 3.

Inspect all parts. See that there are no worn, cracked or distorted clutch plates. All parts must be free of nicks, burrs or any imperfections that will reduce the efficient operation of the unit.

1. Assemble differential as suggested in Figs. 1, 2 and 3.
2. Make sure the side gear retainer will rotate with a slight drag when in the case. Repeat for opposite side.

Fig. 1 Plate clutch type of POWR-LOK differential (4 stack unit) with Belleville spring plates at outside of stacks. Install Belleville plate with convex side toward case

Fig. 2 Plate clutch type of POWR-LOK differential (5 stack unit) with Belleville spring plates in center of stacks. Install Belleville plate with convex side toward case

Fig. 3 Plate clutch type of POWR-LOK differential (5 stack unit) with Belleville spring plates at outside of stacks

3. Install side gear on ring gear flange half.
4. With ring gear flange half in a vertical position, install one shaft and gears, making certain that notch in shaft is up.
5. Install side gear in other half of case.
6. Hold the remaining case half through the bearing trunnion and install it on the ring gear flange half, being sure scribed mark made previously is in alignment.
7. Insert axle shafts to align side gear

Fig. 4 Aligning splines of side gear and side gear ring before tightening attaching bolts

Fig. 6 Cross section of Corvair locking differential

ring with bevel side gear, Fig. 4. If this is not done there may be some difficulty when installing axle shafts during final assembly. Tighten attaching bolts evenly to 35-45 ft. lbs.

8. Check clearance between pinion mate shaft and the V of the case, Fig. 5. Do this by placing shim stock or feeler gauges on both ends of the same shaft and on opposite sides of the V. The clearance should be from zero to .020″ maximum.

Installation Note

Make sure the spline end of the axle shaft does not interfere with the pinion mate shafts. This can be checked with a steel tape by measuring from the bottom of the axle shaft bearing bore to the pinion mate shafts. Then measure the axle shafts from the corresponding point of the bearing to the end of the spline. The minimum clearance required is ⅛″. Grind off the spline end of the axle shaft if it is too long. Check the other axle shaft in the same manner.

CAUTION: Use rear axle lubricant of the type specially recommended for locking differentials. Failure to use the proper lubricant will result in chattering or other serious malfunction.

CORVAIR TYPE

This type locking differential, Fig. 6, uses a clutch pack only on one side of the differential. Disassemble as follows:

1. Remove ring gear from differential case.
2. Chisel or punch alignment marks on case and cover, remove two flathead screws and separate case and cover.
3. Remove right-hand side gear, clutch pack preload spacer and clutch pack.

Assembly

1. Lightly oil clutch plates and side gear. Install clutch pack in differential cover in sequence shown in Fig. 7.
2. Install side gear in clutch pack, making sure its splines engage clutch plate splines.
3. Align differential case and cover and assemble ring gear with improvised guide pins. Remove guide pins and install ring gear bolts, drawing case and cover together. Tighten bolts to 40-60 ft. lbs.

Clutch Pack Preload Test

1. Clamp differential assembly in a vise with soft jaws.
2. Insert a spare disassembled axle shaft yoke into one side gear. Slide a piece of 1″ bar stock at least 14″ long into yoke, Fig. 8.
3. With scale positioned 12″ from centerline, check torque necessary to rotate yoke and side gear. Torque reading should be 50-70 ft. lbs.

Fig. 5 Checking clearance between pinion mate shaft and V in case. Feeler gauges must be inserted on both ends of same shaft and on opposite sides of V

FORD TYPE

Disassembly

1. Referring to Fig. 9, mark one differential bearing cap and the mating support to help position the parts properly during assembly of the carrier.
2. Remove bearing adjusting nuts and lift differential assembly out of carrier.
3. Remove differential bearings.
4. Loosen *alternate* drive gear attaching bolts evenly to release the spring pressure between differential case and cover.
5. Remove differential case cover and then the drive gear.
6. Remove clutch plates.
7. Remove two Belleville springs.
8. Remove clutch hub, side gear and thrust washer.
9. Drive out differential pinion shaft lock pin.
10. Drive out differential pinion shaft. Then remove pinion gears and thrust washers.

Fig. 7 Exploded view of Corvair locking differential

Fig. 8 Checking clutch pack preload on Corvair locking differential prior to installation

Fig. 9 Ford type locking differential

Fig. 10 Rambler Six locking differential of the cone clutch and thrust block type

Fig. 11 Dana cone type locking differential disassembled

Assembly

1. Lubricate all parts during assembly. Referring to Fig. 9, place side gear and thrust washer in differential case.
2. With soft-faced hammer, drive pinion shaft into case only far enough to retain a pinion thrust washer and pinion gear.
3. Place a second pinion and thrust washer in position, and drive pinion shaft into place. *Carefully line up pinion shaft retainer holes.*
4. Place second pinion and thrust washer in position. Drive pinion shaft into place. Install pinion shaft retainer. *The retainer must not extend beyond the machined surface of the case.*
5. Insert two 2"x$\frac{7}{16}$" bolts through differential flange and thread them 3 or 4 turns into the drive gear as a guide in aligning drive gear bolt holes. Press or tap drive gear into position.
6. Clamp differential case in a vise. Install differential side gear on pinion gears. Place clutch hub on side gear and place thrust washer on hub.
7. Insert two $\frac{3}{16}$x2" dowel pins into differential case. Place a steel plate on differential case so that slots in dog ears straddle dowel pins. *Lubricate all differential parts so that an accurate torque check can be made.*
8. Place a bonded plate on steel plate. Make sure bonded plate inner spline teeth properly engage hub spline. Assemble remaining plates: a steel plate, a bonded plate and lastly a steel plate.
9. Place two Belleville springs on the top steel plate. Both springs are assembled with concave sides down.
10. Place differential case cover on case and start bolts.
11. Tighten bolts evenly and alternately across the diameter of drive gear. As the bolts are tightened the Belleville springs are compressed and the case and cover are pulled together.
12. Torque the bolts to 65-75 lb. ft.
13. Check torque required to rotate one side gear while the other side gear is held. Ignore the torque required to start the side gear turning. The torque required to keep it moving steadily should be between 155 and 195 lb. ft. If not within these limits, check for improper assembly.
14. Install differential in carrier.

CAUTION: Use rear axle lubricant of the type specially recommended for locking differentials. Failure to use proper lubricant will result in chattering or other serious malfunction.

RAMBLER TYPE

In this type, Fig. 10, the locking action is accomplished by two spring-loaded thrust blocks which bear against each side gear, which in turn are seated in a tapered cone that clutches inside each case half. The spring load is calibrated to be rendered ineffective by variable torque; that is, when turning corners, the torque created on one wheel by differential action will overcome the spring load of the thrust blocks on the side gears.

Service Check

To avoid unnecessary disassembly, the effectiveness of the unit may be checked as follows:

Place the transmission in neutral with the engine turned off and jack up one rear wheel only. Turn the raised wheel in a forward motion with a socket and torque wrench on the axle shaft nut. A torque reading of 80 to 120 ft. lbs. should be attained before the wheel will slip. If reading falls within this range, the assembly is in proper operating condition.

Servicing The Unit

The locking differential will be serv-

iced only as a complete unit assembly. When replacement is required, follow the service procedure for the conventional type axle except when working on the differential unit itself. To service the differential unit, proceed as follows, referring to Fig. 10.

1. Separate case halves and inspect parts. The cone seat in the case should be slightly grooved. The male cone surface should be grooved similar to a transmission synchronizer friction ring. Excessive wear or damaged cone surfaces warrants replacement.

CAUTION: When reassembling the unit, use axle shafts as mounting tools to assure proper gear and cone spline alignment. Do not ignore this procedure as it will be impossible to install shafts at final assembly. Attempting to force the shafts into position may result in breakage of the spring thrust blocks.

2. Clamp one axle shaft vertically in a vise, allowing 3″ to extend above vise jaws.
3. Place ring gear flange side of differential case over extended axle shaft with interior of case facing up.
4. Note that cones are stamped "flange" and "cap" on back side. The tapers and surfaces are match fitted.
5. Install cone stamped "flange" into flange half of case over axle shaft splines into proper position.
6. Place washer and side gear over axle shaft and allow it to seat on cone mounting face.
7. One spring thrust block is then placed in position over gear face in alignment with pinion gear thrust grooves. Install pinion shaft, axle shaft thrust block, pinion gears, and thrust washers into flange half of differential case in such a manner that the pinion shaft retaining dowel can be inserted through the pinion gear shaft and into differential case. This prevents the pinion shaft from sliding out and causing damage to the carrier assembly.
8. Insert springs into spring pockets and place second thrust block over springs.
9. Align second side gear to mesh with pinion gears face down on thrust block.
10. Place side gear washer and remaining cone stamped "cap" over side gear.
11. Install cap side of differential assembly over cone in proper position and insert two bolts 180° apart to finger tightness.
12. Install other axle shaft through cap side of differential case, turning it to enter cone splines and then side gear splines. Leaving the axle shaft in this position, insert remaining bolts and torque to 15-18 ft. lbs.
13. Remove the axle shafts. A slight tapping on the shafts with a soft hammer may be necessary to overcome the binding action of the splines during assembly. The shafts can then be readily installed without spline interference at the proper point in final assembly.
14. Install the unit in the axle housing as you would with a conventional differential.

Fig. 12 Installing parts in cap half of differential case

Fig. 13 Installing preload springs and thrust block in differential case

Fig. 14 Installing flange half of differential case

CAUTION: Use rear axle lubricant specially recommended for locking differentials. Failure to use proper lubricant will result in chattering or other serious malfunction.

NOTE

After the unit is installed in the housing, do not attempt to rotate one axle shaft until both are in position. Rotation of one axle shaft without the other shaft installed will result in misalignment of cone and side gear splines and prevent entry of the second axle shaft.

DANA CONE TYPE

This unit, Fig. 11, has spiral-threaded cone brakes installed behind the differential side gears. These brakes are statically spring preloaded to provide an internal resistance to differential action within the case itself. This preload assures an adequate amount of pull under extremely low tractive conditions.

Disassembly

1. Clamp case in vise by ring gear or by case flange.
2. Mark flange half of case and cover half with a center punch or paint to provide alignment for reassembly.
3. Loosen bolts holding cover case halves. Remove assembly from vise and remove bolts.
4. Remove parts from each case half, keeping all parts, including side gear shims if present, together with their respective half.

Inspection

1. Clean parts thoroughly.
2. Inspect pinion shaft, pinion and side gears, brake cone surfaces and corresponding cone seats in case. Cone seats in case should be smooth and free of any excessive scoring. Slight grooves or scratches indicating passage of foreign material are permissible and normal. The land surfaces on the heavy spirals of the male cones will duplicate the case surface condition.
3. Replace any parts that are excessively scored, pitted or worn. Both halves of case must be replaced if one half is damaged or worn.

Reassembly

CAUTION: When assembling the unit, use axle shafts as mounting tools to assure proper gear and cone spline alignment. Do not ignore this procedure as it will be impossible to install shafts at final assembly. Attempting to force axle shafts into position may result in damage to spring thrust blocks.

1. Clamp one axle shaft in vise allowing three inches to extend above vise jaws. Then place cap side of case over axle shaft with interior of case up.
2. Install proper cone over axle shaft splines, seating it into position in cap half of case.

NOTE: Be certain that each cone is installed in proper case half since tapers and surfaces become matched and their positions should not be changed.

3. If unit was originally assembled with shims located between side gears and cones for backlash adjust-

Fig. 15 Dana plate-type locking differential used on all 1964 and early 1965. Unit used on late 1965 and 1966-67 differs in that the clutch plates have ears and only two springs are used instead of the four shown. Two-spring units must be assembled with springs 180° apart. Use Allen head wrench to remove differential lock pin

ment, reinstall side gear with shim so that gear may seat on shim. If no shims were originally used, reassemble the same way.

4. Place one spring block in position over gear face in alignment with pinion gear shaft grooves.
5. Install thrust block, pinion shaft, gears and thrust washers in such a manner that pinion shaft retaining dowel can be inserted through pinion shaft into differential case. This prevents pinion shaft from sliding out and causing damage to carrier assembly, Fig. 12.
6. Insert springs into spring thrust block and then place second thrust block over springs, Fig. 13.
7. Install second side gear face down on spring thrust block so that side gear will mesh with pinion gears.
8. Place shim, if provided, and remaining cone over side gear.
9. Install flange side of assembly over cone in proper position to match alignment marks. Insert two bolts finger tight 180 deg. apart, Fig. 14.
10. Install other axle shaft through flange half of case, rotating axle to enter cone splines and then side gear splines. Leaving axle shaft in this position insert remaining bolts and torque to 15-18 ft-lbs.
11. Remove axle shafts. A slight tapping on shafts with a soft hammer may be necessary to align splines during assembly. The shafts can then be reinstalled without spline interference during final assembly.
12. Install unit in axle carrier.

CAUTION: After unit is installed in carrier, do not attempt to rotate one axle shaft until both are in position. Rotation of one shaft without the other installed will result in misalignment of cone and side gear splines and may prevent entry of second axle shaft.

13. Test differential operation as outlined at the beginning of this chapter.

DANA PLATE TYPE

Disassembly, Fig. 15

1. Remove ring gear and install spring tool shown in Fig. 16, making sure spring jaws are securely indexed between spring coils.
2. Compress tool until spring is compressed enough to slide out of retainer seats. Repeat on remaining springs.
3. Remove differential pinions by rotating side gear with axle shaft until they move around to large opening in case. Pry clutch pack away from pinion until pinion drops out. Remove pinion thrust washers.
4. Remove clutch packs and side gears.

Inspection

1. Clean and inspect side gear thrust surfaces, pinion gear thrust surfaces and thrust washers for excessive wear and replace as required.
2. Inspect clutch pack for excessive wear or overheating and, if necessary, replace as a unit.

Fig. 16 Spring removal

Reassembly

1. Place clutch pack cages into case with side tabs up and flat sides parallel with flat sides in case.
2. Place aluminum spring seat plate over side gear.
3. Alternately place clutch plate and clutch disc on side gear until assembly of pack is complete. Make sure clutch discs index with teeth in side gear.
4. Install clutch pack and side gear assemblies in case. Tilt case on its side to prevent side gears from falling out.
5. Place pinion gear between side gears through large opening in case. Rotate side gears and install second pinion directly opposite first. Install pinion thrust washers.
6. Place clutch spring in jaws of tool shown in Fig. 16. Compress spring to about 1.90″ and carefully insert into spring seats. Release spring and remove tool. Repeat for remaining springs.
7. Install ring gear.
8. Place differential in carrier.
9. Test operation of differential as outlined at the beginning of this chapter.

EATON TYPE

Disassembly, Fig. 17

1. Remove pinion shaft lock screw and pull pinion shaft from case.
2. Remove preload spring retainer and springs.
3. Rotate side gears until pinions are in open area of case and pick out pinions and thrust washers.
4. Remove a side gear, clutch pack and shims, noting shim location in case to aid in reassembly. Remove side gear clutch pack and shims from opposite side. If side gear or clutch

Fig. 17 Eaton plate-type locking differential. Two preload springs (shown) are used on intermediate-size cars; four preload springs are employed with full-size car applications

Fig. 18 Removing side gear

Fig. 19 Checking side gear-to-piston backlash

Fig. 20 Oldsmobile Type "O" locking differential

pack cannot be removed readily, drive it out with a brass drift, Fig. 18.

5. Remove clutch plate guides and separate shims and clutch plates from side gears.
   Note: Keep clutch plates in their original location in clutch pack.

Inspection

1. If pinion shaft, pinions or side gears are excessively scored, pitted or worn, replace parts affected.
2. Inspect clutch plates for scored, worn, cracked or distorted condition. If any of these conditions exist, new clutch plates must be installed.

Reassembly

1. Alternately position nine clutch plates on side gear, starting and ending with a plate with external lugs.
2. Install two clutch guides over clutch plate lugs.
3. Install same shims which were removed or an equal amount on clutch plate.
4. Repeat above steps on other clutch pack.
5. Install one side gear with clutch pack and shims in case.
6. Position two pinion gears and thrust washers on side gear and install pinion shaft.
7. Compress clutch pack by inserting a screwdriver or wedge between side gear and pinion shaft.
8. Install a suitable dial indicator with contact button against pinion gear, Fig. 19.
9. Rotate pinion gear. Clearance should be .001″ to .006″.
10. If clearance is more than .006″, add shims between clutch pack and case. If clearance is less than .001″, remove shims. A .002″ shim will change clearance about .001″. Recheck clearance after adding or subtracting shims.
11. Remove side gear and repeat procedure with remaining clutch pack on opposite side of case.
12. Remove pinion shaft, pinions and thrust washers.
13. Install remaining side gear and clutch pack with correct shims in case.
14. Place pinion gears on side gears and rotate into correct position.
15. Compress preload springs and drive preload retainer and springs between side gears.

Fig. 21 Checking side gear-to-pinion backlash

Fig. 22 Removing or installing pinions and thrust washers

16. Insert thrust washers behind pinion gears.
17. Install pinion shaft and retain with lock bolt, tightening lock bolt to 15-25 ft-lbs.
18. Check side gear splined hole to be certain it is in line with hole in preload spring retainer. Spring retainer can be moved slightly to correct alignment.
19. Test operation of differential as outlined at the beginning of this chapter.

OLDSMOBILE TYPE "O"

Disassembly, Fig. 20

1. Remove pinion shaft lock screw, then remove pinion shaft from case.
2. Remove clutch plate guides and separate shims and clutch plates from side gears. Keep clutch plates in their original location in clutch pack.
3. Clean and inspect all parts and replace as required.

Reassembly

1. Apply recommended lubricant to clutch plates.
2. Alternately position clutch plates on side gear, starting and ending with a clutch plate having external lugs.
3. Place spacer against plate having external lugs, then install shims. *Make sure to install the same spacer and shims or an equal amount on the clutch pack for a starting point.*
4. Repeat foregoing procedure on other clutch pack.
5. Install one side gear with clutch pack and shims in case.
6. Position two pinion gears and thrust washers on side gear and install pinion shaft.
7. Compress clutch pack by inserting a screwdriver between side gear and pinion shaft.
8. Install dial indicator with contact button against pinion gear, Fig. 21.
9. Rotate pinion gear; clearance should be .001 to .006".
10. If clearance is more than .006", add shims between clutch pack and case. If clearance is less than .001", remove shims. A .002" shim will change clearance about .001". Recheck clearance after adding or subtracting shims.
11. Remove side gear and repeat procedure with opposite clutch on opposite side of case.
12. Remove pinion shaft, pinions and thrust washers.
13. Install remaining side gear and clutch pack with correct shims in case.
14. Place pinion gears on side gears and rotate into correct position, Fig. 22.
15. Install thrust washers behind pinion gears and align.
16. Insert pinion shaft into case, through thrust washer and part way into pinion gear. This will keep pinion gears aligned while driving preload spring into place.
17. Position preload spring as shown in Fig. 23, next to side gears and drive into place.
18. Push pinion shaft into position and align lock screw hole in shaft with hole in case. Install lock screw and torque to 15 ft-lbs.

SERVICE NOTES

Differential Chatter

Locking differential chatter is usually more likely to be caused by a lubrication problem than a mechanical problem. The condition can often be corrected by simply driving the vehicle in 5 fairly tight circles clockwise and then in 5 circles counter-clockwise. This allows the lubricant to work in between the clutch plates which should provide smooth operation. However, if chatter still exists, proceed as follows:

Fig. 23 Installing preload spring

1. Siphon the lubricant from the axle and refill with a lubricant specifically designed for these axles. The vehicle should then be driven 25-50 miles at which time the chatter should disappear. If the chatter still exists proceed with step 2.
2. Disassemble and clean the differential carrier. Install new friction plates which have been soaked for ½ hour in the special lubricant. Reassemble the differential and install in vehicle. Refill the axle with special lubricant and drive vehicle in tight circles in both clockwise and counter-clockwise directions. If chatter still exists, the vehicle must be driven 25-50 miles to allow the lubricant to work in between the plates. The chattering should then disappear.

FUNDAMENTALS OF REFRIGERATION

In order to understand how an air conditioning system works, we must have a knowledge of the fundamentals of refrigeration. And since refrigeration is the process of removing heat from things, an air conditioner removes heat from the surrounding air. In both cases, the process is simplified by one of Nature's laws—heat always moves from a warm object to a cold object.

When we put milk or vegetables into an ice box, they are warmer than the ice. Since heat always travels from warmer to cooler objects, the heat in the milk and vegetables naturally travels to the cold ice. Then, of course, as heat is removed from these articles, they begin to grow cooler—they have less heat than before.

Therefore, if refrigeration is the removal of heat, then anything can be made cooler by finding a method of absorbing heat from it.

In order to maintain cold temperatures, we have to have continuous refrigeration. This is accomplished in modern refrigerators and cooling systems (1) by using a refrigerant that will readily absorb heat and (2) by using the same refrigerant over and over.

Ice can refrigerate effectively *only when it is changing from a solid to a liquid.* A liquid can refrigerate *only when it is changing from a liquid to a vapor.* A vapor cannot refrigerate since the absorption of heat will not change it to any other state. The only thing to do with a vapor is to change it back to a liquid—by removing heat from it.

In other words, if the ice didn't melt, it could absorb a little heat from the objects and the air around it but not enough to do an effective job of cooling. But when it begins to change to a liquid (water), then the ice is absorbing heat rapidly and effectively.

The same applies to a liquid refrigerant. No matter how cold the liquid is, it won't actually "refrigerate" until it is absorbing heat fast enough to change its form into a vapor.

Operating Cycle of Car Air Conditioning System

1. The compressor compresses heat-laden, low-pressure vaporous refrigerant and discharges it into the condenser.
2. In the condenser, the vapor changes into a liquid as the heat is dissipated into the surrounding air.
3. From the condenser, the liquid is forced into the reservoir or receiver, which is simply a storage container the function of which is to ensure a supply of *liquid* Freon to the expansion valve. (The expansion valve functions in much the same manner as a hose nozzle).
4. From the reservoir, the liquid Freon passes through a combination strainer-drier, then through the expansion valve into the evaporator.
5. Being connected to the suction line of the compressor, the evaporator is a low-pressure region in which the refrigerant boils and reverts to a vapor, absorbing heat in the process and thereby cooling the evaporator coil and the air passing over it.
6. Upon leaving the evaporator, the vaporous refrigerant returns to the compressor inlet and completes the refrigeration cycle.

EXERCISE SYSTEM

An important fact most car owners ignore is that car coolers must be used periodically or they will go sour. Car manufacturers are emphatic on this point. They caution that, when the air conditioner is not used regularly, particularly during cold months, it should be turned on for a few minutes once every two or three weeks while the engine is running. This keeps the system in good operating condition.

Checking out the system for the effects of disuse before the onset of summer is one of the most important aspects of car cooler servicing.

AIR CONDITIONING

Air conditioning cycle of operation

How air conditioner works

First on the list is to clean out the condenser core, mounted in all cases at the front of the car's radiator. All obstructions, such as leaves, bugs, dirt, and the like, must be removed, as these will reduce heat transfer and impair the efficiency of the system. Make sure the space between the condenser and the radiator also is free of foreign matter.

Make certain the evaporator water drain is open. Certain systems have two evaporators, one in the engine compartment and one in the trunk. The evaporator is the device which cools and dehumidifies the air before it enters the car, and the place where refrigerant is changed from a liquid to a vapor. As the core cools the air, moisture condenses on it but the moisture is prevented from collecting in the evaporator by means of the water drain.

TROUBLE DIAGNOSIS

Insufficient or No Cooling

The first unit to check is the blower mechanism and its air-distribution system, since the cooling is produced by a combination of a cool evaporator and a blower to circulate the cooled air. If the blower is inoperative, check for a broken switch, a blown fuse, a loose connection, a broken wire or a defective motor activating the blower mechanism.

In the event the blower is working but the air output is low, look for loose wire connections or shorts, low battery charge, dirty or loose switch contacts or binding of the blower shaft or blades. Also check the air-distribution system for closed air-output valves or obstructions in the flexible hoses.

If the blower is circulating the air efficiently but there is no cooling, the trouble lies in the refrigerating circuit. Beginning at the source of power, check the compressor driving belt. Is it loose, slipping or broken? If the belt is tight and the pulley is turning but the compressor shaft is not, check the magnetic clutch for lack of current or a faulty coil.

A steady, resonant noise from the compressor is normal but any clicking or rattling sounds should be investigated. Using a standard set of twin gauges, check the compressor inlet and outlet pressures according to manufacturer's specifications. If the normally high outlet pressure is not up to specs, it is probably due to a low charge of coolant, excess moisture in the system, or a restriction or kink in the circulation lines.

Be sure that there is sufficient compressor oil of the proper viscosity. At the same time, make certain that there is no excess oil from the compressor flowing through the system, slowing coolant circulation and reducing compressor outlet pressure.

If the normally low inlet-suction pressure is high but the outlet pressure is normal, there is probably trouble either at the expansion valve, which controls the amount of fluid entering the evaporator, or with the sensor bulb that controls the expansion valve. Other causes would include excess moisture in the system or a defective suction throttle valve (if used) on the compressor.

Excessive vibration of the compressor indicates loose mounting bolts or an out-of-true belt pulley. A thumping noise from the compressor or a cool and sweating suction line into it, is usually caused by too much coolant in the system. Should there be no moisture in the system, evacuate the excess coolant into the atmosphere.

Check Condenser

If the condenser unit, located in front of the radiator, is suspected, the first thing to look for is clogged coils that limit the cooling capacity of the unit. Any bugs, leaves or debris caught in the coils should be removed by air pressure. In the event there is any icy or frosty spots apparent on the exterior of the condenser, they usually indicate a partial restriction inside the condenser at that point.

Check Sight Glass

The next spot to check in the refrigerating circuit is the line sight glass (if used). This small transparent device permits a visual check of the condition of the high-pressure liquid coolant. A cloudy, foamy appearance, or the presence of bubbles in the fluid, indicates air or excess moisture in the lines, or a low charge of coolant.

Check Receiver-Dehydrator

Sometimes fault will be found in the receiver-dehydrator unit, usually located alongside the condenser. This small storage unit for the coolant also contains an element for removing small amounts of moisture from the refrigerant and has a filtering element for catching small dirt particles.

If the system has been in operation for a considerable period of time, this dehydrating element may lose its moisture-absorbing ability. This condition causes the constant presence of small bubbles in the sight glass. It is also indicated when the high-pressure line into the dehydrator has a distinctly different temperature from that of the outlet line. This receiver-dryer component should be replaced as a unit if the above symptoms are observed, if all other parts of the system are in good operating condition, and the system is fully charged.

Check Evaporator

The proper functioning of the evaporator is always dependent on an efficient expansion valve at the intake end and an efficient sensor bulb and (if used) a suction throttle valve at the outlet end of the coils. In normal operation, this unit should be cold and sweating, but not iced. Icing calls for a check of the expansion valve, sensor bulb, or the suction throttle valve (if used).

Since there is a constant condensation of atmospheric moisture on the outside of the evaporator coils, make sure that the draining system is free and clean and able to dispose of the collected water through the car floor.

NOTE: Some of the larger, more expensive cars have a supplementary evaporator unit in the luggage compartment. Don't forget to check the operation of this unit.

Testing System for Leaks

Testing the system for leaks is one of the most important over-all phases of trouble-shooting an air conditioning system. There are several methods of performing this operation which is explained elsewhere in this chapter.

If there is a loss of refrigerant and no external leak can be found, gas might be leaking from a damaged piston diaphragm in the suction throttle valve (if used). In this case, vapor would be drawn into the engine intake manifold and be burned, undetected in the cylinders.

Refrigerant Dangerous

A final word of caution. The freon refrigerant used in car air-conditioners is also known as R-12 or F-12. It is colorless and odorless both as a gas and a liquid. Since it boils (vaporizes) at 21.7 deg. F., it will usually be in a vapor state when being handled in a repair shop. But if a portion of the liquid coolant should come in contact with the hands or face, remember that its temperature momentarily will be at least 22 deg. below zero!

Protective goggles should be worn when opening any refrigerant lines. If liquid coolant does touch the eyes, bathe the eyes quickly in cold water. Then apply a bland disinfectant oil to the eyes. See an eye doctor.

TROUBLE SHOOTING GUIDE

NOTE: When a unit must be removed from the system for replacement or repairs, the dehydrator must be replaced also, and the system must be purged, evacuated and recharged to remove excess moisture.

System Produces No Cooling

Electrical
1. Blown fuse.
2. Disconnected or broken wire.
3. Disconnected or broken ground wire.
4. Clutch coil disconnected or burned out.
5. Switch contacts in thermostat (if used) burned excessively, or sensing element defective.
6. Blower motor burned out or disconnected.

Mechanical
1. Loose or broken drive belt.
2. Compressor completely or partially frozen.
3. Compressor reed valves inoperative.
4. Expansion valve stuck open.

Refrigeration
1. Broken refrigeration line.
2. Fusable plug blown (if used).
3. Leak in system.
4. Compressor shaft seal leaking.
5. Clogged screen or screens in receiver-dehydrator or expansion valve.
6. Plugged coil or hose.

Insufficient Cooling

Electrical
1. Blower motor operates sluggishly.

Mechanical
1. Compressor clutch slipping.
2. Obstructed blower discharge passage.
3. Clogged air intake filter.

Fig. 1 Chrysler Air-Temp gauge set manifold connections used with V2 compressors

Fig. 2 Manifold gauge set for Frigidaire, Tecumseh and York compressors

4. Outside air vents open.
5. Insufficient air circulation over condenser coils; fins clogged with dirt, leaves or insects.
6. Evaporator clogged.
7. Evaporator regulator defective or improperly adjusted.

NOTE: The evaporator regulator includes the hot gas by-pass valve used on most General Motors cars prior to 1962, suction throttling control valve (STV) used on 1962-65 General Motors cars, the Pilot Operated Absolute (POA) valve used on 1966-67 General Motors cars, and the Chrysler Evaporator Pressure Regulator (EPR) valve. When any of these devices are used in a system, it can be assumed that the system contains no thermostat-control.

Refrigeration

1. Insufficient refrigerant in system.
2. Clogged screen in expansion valve.
3. Expansion valve thermal bulb has lost its charge.
4. Clogged screen in receiver.
5. Excessive moisture in system.
6. Air in system.
7. Thermostat defective or improperly adjusted (if used).

System Cools Intermittently

Electrical

1. Defective circuit breaker, blower switch or blower motor.
2. Partial open, improper ground or loose connection in compressor clutch coil.

Mechanical

1. Compressor clutch slipping.

Refrigeration

1. Unit icing up; may be caused by excessive moisture in system, incorrect super-heat adjustment in expansion valve, or thermostat adjusted too low (if used).
2. Thermostat defective (if used).
3. Stuck hot gas by-pass valve, STV, POA or EPR valve.

OIL LEVEL CHECK

Air-Temp, Tecumseh & York Compressors

1. Connect gauges into system, Figs. 1 and 2. Adjust controls to maximum cooling. Then operate system for 10 to 15 minutes to stabilize at 1500-1750 rpm.
2. Isolate compressor from system as outlined later on. *This does not apply to systems not having a low side compressor service valve.*
3. Close low side service valve slowly until pressure drops to zero. Shut off car engine. Completely close low side service valve. Close high side service valve.
4. Wear a face shield. Then remove oil check plug slowly to bleed off a small refrigerant charge in compressor. Remove cap after gauge reads zero. Determine correct oil level by referring to the *A/C Data Table.*
5. Add refrigeration oil as required to bring to correct level.
6. Replace oil check plug, and center service valves.

Frigidaire Compressors

NOTE: These compressors have no provision accurately to check oil level on the car. Periodic inspection of oil level has, therefore, been eliminated from installations using this compressor. Oil level check performed with the compressor removed from the car is to be made only under conditions of severe oil loss caused by a compressor oil leak, broken refrigerant hose, or a rupture from crash damage. The system is designed to hold the quantity of refrigeration oil listed in the *A/C Data Table.* The affinity of Freon 12 and refrigeration oil and the design of the compressor will prevent a full oil charge being contained in the compressor.

1. Purge refrigerant from compressor.
2. Remove compressor from car.
3. Remove oil from compressor.
4. Remove plug on pump.
5. Pour oil from compressor into a clean container calibrated in ounces.
6. Measure oil removed from compressor.
7. Install new oil into compressor. Install plug and tighten.
8. Install compressor on car. Repair damage to system as required to eliminate leaks. Evacuate system, using a suitable vacuum pump. Then charge system with new Freon 12.

Oil Distribution

Whenever a component of the A/C system is replaced, measured quantities of refrigeration oil should be added to the component to assure that the total oil charge in the system is correct before the unit is placed into operation.

The oil is poured directly into the replacement component. If an evaporator is installed, pour oil into the inlet pipe with the pipe held vertically so the oil will drain into the evaporator core. No additional oil is required if valves and hoses are replaced.

1. If the oil drained from the compressor is more than 4 fluid ounces, add to the new compressor the same amount of oil as drained from the replaced unit.
2. If oil drained from the compressor is less than 4 fluid ounces, add 6 ounces of oil to the new compressor.
3. Oil should be added to replacement components as follows:
   Evaporator (front or rear) . add 3 oz.
   Condenser . . . . . add 1 oz.
   Receiver . . . . . add 1 oz.
   Condenser-receiver assembly add 2 oz.

NOTE: If the system is flushed with sufficient quantity of a flushing agent that would remove oil from the system, install the full amount specified in the *A/C Data Table.* On a newly installed

Fig. 3 Wiring diagram of a typical adjustable thermostatic switch

Fig. 4 Schematic layout of a thermostatic-controlled clutch circuit

system, install the full capacity of oil prior to operation. On systems containing metal particles in the oil, replace or overhaul the compressor, replace the receiver-dehydrator and install a high capacity, low pressure drop filter in the liquid line to the filter to protect the expansion valve and new compressor from damage due to foreign particles.

THERMOSTAT CONTROL SWITCH

When an A/C system is not provided with a hot gas by-pass valve or a suction throttling valve (STV, POA or EPR), the pumping action of the compressor is stopped by a thermostatically-controlled switch, Figs. 3 and 4.

The opening and closing of the electrical contacts are controlled by a movement of a temperature sensitive diaphragm or bellows. The bellows has a capillary tube connected to it which is filled with Freon or CO_2. The capillary tube is positioned so that it may have either the cold air from the evaporator pass over it or it may be connected to the tail pipe of the evaporator. In either position, evaporator temperature will affect the temperature-sensitive compound in the capillary tube by causing it to contract as the evaporator becomes colder. The contraction of the gas will cause the bellows to contract. This action separates the electrical contacts and breaks the electrical circuit to the compressor clutch, which stops compressor operation.

The evaporator begins to warm which, in turn, causes the gas in the capillary tube to expand. The bellows will also begin to expand, moving the electrical contacts closer to each other At a predetermined point, the expansion of the bellows will bring the contacts together, closing the circuit to the compressor clutch, energizing it and bringing the compressor into operation again. This cycling action will be repeated as long as air conditioning operation is required.

Thermostat, Adjust

Visual inspection must be made to determine if a thermostat is adjustable. All thermostats have a provision for regulating the range between opening and closing the contacts. Some models may have a removable fiber cover under which will be located the adjusting screw. If a set screw is not found here, it may be assumed that the thermostat is not adjustable.

All types, whether or not they have an internal adjustment, have a provision whereby the spring tension and contact spacing may be varied by the driver to regulate evaporator cooling. Temperature control is accomplished by rotating a cam which will increase or decrease spring tension on a pivoting contact hanger. Rotation is accomplished either by movement of a stem on which a knob is fastened or it may be accomplished by a cable arrangement. On thermostats that are adjustable, the procedure is as follows:

1. Connect gauges into the system and adjust A/C controls for maximum cooling.
2. Operate engine for 10 to 15 minutes to stabilize at 1500-1750 rpm.
3. Read high side gauge for full refrigerant charge, which will read high side pressure approximating the temperature-pressure relationship shown in Fig. 5.
4. Check sight glass for absence of bubbles.
5. Read low side gauge for thermostat operation. It should read from 26 psi to 14 psi after system has been stabilized for 10 to 15 minutes.

NOTE: The thermostat should disconnect the compressor clutch for evaporator defrost between high and low readings. If the thermostat will not recycle the clutch, move the temperature control toward the warmer position to check for thermostat contact opening.

6. Count number of psi required for warm-up until contacts close, which should indicate 26 to 32 psi rise between contact opening and reclosing. Check the thermostat at least 3 times for consistent operation.

NOTE: Thermostats are generally but not always located in the evaporator case. A certain amount of diligence will be required to locate the thermostat, especially with some models of luggage compartment units.

7. Remove parts as required to gain access to the thermostat. Open access door to the adjusting screw. Rotate adjusting screw counterclockwise to lower contact opening, and clockwise to raise point opening pressure.

NOTE: Localities having high mean humidity will require higher contact opening pressure than localities with low mean humidity. Coastal areas with contact opening adjustment lower than 24-26 psi will result in evaporator freeze-up. So-called desert areas with very low humidity can easily tolerate contact opening adjustment of 14-16 psi without evaporator freeze-up.

8. Check operation of thermostat for newly adjusted cycle of operation. Replace thermostat if operating cycle is inconsistent or will not respond to adjustment.

SUCTION THROTTLING REGULATORS

Suction throttling regulated systems include any type control used to regulate the flow of refrigerant from the evaporator to the compressor. This control will

be located at some point between the tail pipe of the evaporator and the compressor in the low side or suction line, as it is called.

Sometimes it may be difficult to determine exactly what type of control system is used on a particular installation. However, if under-hood inspection of the compressor and lines does not show a control device, it is safe to assume that a thermostat-controlled recycling clutch is used. *Generally, then, all suction throttling regulator controls will be located under the hood. The thermostat will not be used, and the clutch will be energized during total operation of this type system.*

Constant heat load, ram air, and compressor speed will allow the expansion valve to meter an even flow of refrigerant into the evaporator. Change any of these conditions, however, and the refrigerant flow through the expansion valve will change. Without some means provided to regulate refrigerant flow, the evaporator cooling will become excessive and freeze the moisture condensing on the coils. This results in evaporator icing or freeze-up and requires that the ice on the evaporator be melted before it can resume cooling action.

Installation of a suction throttling control device will compensate for these varying conditions. As the pressure and temperature within the evaporator drop, spring pressure forces a valve within the regulating device toward its seat, retarding the flow of refrigerant. This action increases the pressure back into the evaporator, raising both pressure and temperature. The temperature will not be allowed to drop low enough to freeze over the evaporator coils. A point of balance will soon be reached whereby the refrigerant flow past the valve in the regulator will reach a degree of pressure and temperature sufficient to maintain efficient cooling without evaporator freezing.

Evaporator Pressure Gauge Reading	Evaporator Temperature F°	High Pressure Gauge Reading	Ambient Temperature
0	-21°	45	20°
0.6	-20°	55	30°
2.4	-15°	72	40°
4.5	-10°	86	50°

Fig. 5 Pressure-temperature relationship. Conditions equivalent to 30 mph or 1750 engine rpm

Chrysler Air-Temp EPR Valve

This suction control device, Figs. 6 and 7, is used on many Chrysler units beginning with 1960 models. The EPR valve (Evaporator Pressure Regulator) is calibrated to produce maximum "cooling" without causing frost or ice on the evaporator fins and tubing. If for any reason the factory calibration has been disturbed, the EPR valve may restrict the flow of refrigerant at an evaporator pressure which is either too high for maximum performance or too low to prevent coil freeze-up. The following test determines whether or not the valve is functioning properly.

Testing EPR Valve

1. Connect gauge set as illustrated in Fig. 1.
2. Operate engine for 10 to 15 minutes to stabilize system at 1300 rpm (800 on Imperial). Adjust A/C controls for maximum cooling.
3. Open windows and hood. The EPR valve is operating correctly when gauges read 26 psi.
4. The next step is to determine the minimum evaporator suction pressure maintained in the suction line by the EPR valve. The EPR valve action can be accelerated by reducing the heat load on the evaporator by setting the blower switch to the "Low Speed" position and set the A/C control for maximum cooling.
5. Read both low pressure gauges. Evaporator pressure should drop and settle at 22 to 26 psi. Compressor inlet pressure will fluctuate (modulation of EPR) and settle at 15 psi or less, Fig. 8. If pressure will not drop to 15 psi, increase engine speed to 2000 rpm (1700 on Imperial).
6. The suction gauge pressure should read 22 to 26 psi. This indicates that the suction pressure maintained by the EPR valve is correct. However, if engine speed is increased in order to pull the inlet pressure down to 15 psi, this will also increase suction pressure to 24-28 psi.
7. Repeat foregoing procedure to insure correct operation. Replace EPR valve if pressures are too high or too low.

NOTE: A new EPR valve for 1966 and later models has been incorporated in production. The inner sleeve of the new valve is dampened with a tension spring. This prevents the buzzing noise which exists on some cars, and sounds as if it originates in the evaporator.

If a buzzing noise is encountered on an early 1966 model, or on a 1965 Chrysler, or a 1965 Dodge or Plymouth with 383 engine, install the new EPR valve (No. 2776146).

General Motors STV

Starting with the larger units to be found on General Motors cars beginning with 1962, the STV (Suction Throttling Valve) replaced the hot gas by-pass valve used on earlier models. With the STV the compressor clutch is engaged at all times during system operation as was the hot gas by-pass valve.

A typical installation of the STV is shown in Fig. 9. Manual control in the passenger compartment is accomplished by regulating controlled spring pressure within the STV by means of a vacuum control or a Bowden cable.

The valve is balanced between evaporator pressure and spring pressure. An increase of evaporator pressure and temperature will overcome spring pressure to move the valve away from the seat and increase refrigerant flow. A decreased evaporator pressure and temperature will allow spring pressure to move the valve closer to the seat and retard refrigerant flow. A change in evaporator load will upset the balance between evaporator pressure and spring pressure, causing the valve to reposition itself to compensate for the new requirements of the evaporator.

Fig. 6 Chrysler Air-Temp EPR valve in open position

Fig. 7 Chrysler Air-Temp EPR valve in closed position

Fig. 9 Typical installation showing vacuum-controlled type STV and associated components

Manually-Controlled STV

This type valve, Fig. 10, has an external actuating lever connected to the dash controls by a Bowden cable. An actuating rod connects the lever to the inner mechanism. Two helper springs assist mechanical movement of the actuating lever.

The main function of the valve is to maintain evaporator pressure at a predetermined pressure setting of 29-30 psi, and will maintain the temperature of the evaporator core surface above 32°F.

Vacuum-Controlled STV

The vacuum-controlled STV, Fig. 11, uses a vacuum diaphragm to which an

Fig. 8 EPR valve test pressures

Fig. 10 GM manually-controlled STV

Fig. 11 GM vacuum-controlled STV

actuating pin is attached to the inner mechanism. Modulated vacuum from zero psi to 6 or 7" vacuum is applied to the diaphragm to obtain manual control. The pressure setting, as with the manually-controlled STV, has been established at 29 to 30 psi, and will maintain the temperature of the evaporator core surface above 32°F.

Adjustment Procedure

1. Install gauge set to STV. *The addition of a gauge to the STV will indicate evaporator pressure at this gauge. The compound gauge on the manifold will register STV pressure which may be much lower than evaporator pressure.* Install hose to gauge connector on STV. Use Schrader adapter.
2. With gauges connected into system, adjust A/C controls for maximum cooling. Operate engine for 10 to 15 minutes to stabilize system at 1500 rpm.
3. Force operation of STV. Move "Cold" control lever from maximum to minimum cooling or depress recirculate button. Place blower fan on "Low". Evaporator pressure gauge will register from a low of approximately 28 psi to a high of 35 to 40 psi. Too low an adjustment or a defective valve can cause icing within the STV. If pressure does not change, leave control in minimum cooling position for 10 minutes, then repeat the operation. If gauge readings do not vary, repair or replace the STV.
4. To adjust the STV, set control to maximum "Cold". Use adjusting tool for units having the Bowden control cable, Fig. 12. Loosen lock nut and rotate vacuum units using vacuum control. Clockwise rotation will increase adjusting spring tension to increase evaporator pressure; counterclockwise rotation will decrease spring tension to lower evaporator pressure. Adjust the STV to 28-30 psi.

CAUTION: If evaporator pressure becomes too low during adjustment, the STV may freeze and further adjustment will be ineffective. Move control to minimum cooling for a few minutes until valve thaws, then resume adjustment.

STV With Absolute Vacuum Regulator

This valve, Fig. 13, acts to limit evaporator pressure to a preset minimum, thereby allowing the evaporator to maintain maximum cooling capacity while the system is in operation. This minimum evaporator pressure and temperature is set by means of a spring-loaded adjustment on the valve to a point just above that which would result in freezing of the condensate on the evaporator core. An Absolute Vacuum Regulator attached to the STV, assures that the evaporator pressure will not be allowed to fall below the freeze-up point when the system is operated at higher elevations. Fig. 14 shows the installation of the valve on a 1966 Corvette.

The Absolute Pressure Regulating device acts to maintain a relatively constant pressure (regardless of altitude) in the sealed adjusting spring chamber of the STV, thus minimizing the effect of atmospheric pressure in the operation of the valve.

Checking Operation of STV

1. Attach low pressure gauge line to STV gauge connection, using the proper gauge line adapter.
2. Set up vehicle for Performance Test.
3. Check gauge reading table below for proper suction pressure reading. This pressure will vary according to the elevation at which the test is being made.

Fig. 12 Adjusting manually-controlled STV

Fig. 13 GM STV with Absolute Vacuum Regulator. 1966 Corvette

Fig. 14 STV with Absolute Vacuum Regulator installed on 1966 Corvette

Fig. 15 Typical installation of GM POA valve and associated parts

Fig. 16 Exterior view of POA valve

Altitude	Evaporator Gauge Reading At STV	Vacuum at Press. Reg. Outlet
Sea Level	28.5 psi	9″
900 ft.	29.0 psi	8″
2000 ft.	29.5 psi	7″
3000 ft.	30.0 psi	6″
4000 ft.	30.5 psi	5″
5000 ft.	31.0 psi	4″
6000 ft.	31.5 psi	3″
7000 ft.	32.0 psi	2″
8000 ft.	32.5 psi	1″
9000 ft.	33.0 psi	0″

4. If the pressure reading does not correspond to that listed in the table, proceed as follows to locate the cause of the trouble.
5. Remove vacuum hose to STV and plug end of hose.
6. Remove adjustment screw cap from STV.
7. Again observe evaporator pressure gauge reading which should now be approximately 33 psi regardless of the altitude. If the reading is not 33 psi, turn adjustment screw clockwise to raise (counterclockwise to lower) pressure until proper reading is obtained.
8. If pressure can be adjusted to 33 psi or if it is already at 33 psi, the trouble probably lies with the vacuum hose, vacuum regulator seals, or in the regulator itself.
9. If the valve cannot be adjusted to 33 psi, the main valve assembly should be checked before continuing with the test.
10. Check vacuum hose for split ends or wall cracks which might result in leakage and loss of vacuum.
11. Check cylindrical seal between the STV and regulator and the adjustment screw cover O-ring seal and replace either or both if they are not in good condition. Be sure they are properly positioned to provide a good seal.

Check Vacuum Regulator

1. Remove regulator from STV mounting flange.
2. With engine running, plug vacuum hose into inlet on regulator.
3. Affix a vacuum gauge (such as found on motor test stand) to regulator outlet and check that pressure reading as is shown in foregoing table for the proper altitude.
4. If pressure reading is incorrect, a new regulator should be installed.
5. Reassemble regulator to STV.
6. Install vacuum hose, replace and securely tighten screw cap. Pressure reading should now drop to the value shown in the foregoing table.

Fig. 17 Sectional view of POA valve

Fig. 18 Internally equalized expansion valve

Fig. 19 Externally equalized expansion valve

Checking STV Diaphragm

1. With vacuum regulator removed from the STV, use an engine vacuum line to evacuate the STV adjusting spring chamber through the regulator inlet hose in the center of the mounting flange. If desired, a vacuum pump may be used for this operation.
2. After evacuating, wait about 20 minutes, then check at the hole with the probe of a leak detector. If the presence of refrigerant is detected, the STV diaphragm is defective, and the diaphragm, piston and screen assembly must be replaced.

General Motors POA Valve

The POA valve (Pilot Operated Absolute), Figs. 15, 16, 17, differs from the STV in that it has no vacuum diaphragm. The POA valve will not change calibration when the system is operated at a higher altitude due to the atmospheric pressure to which the STV was subjected because of its vacuum diaphragm.

NOTE: When it is found necessary to replace a POA valve, check the interior of the defective valve for corrosion or crystalization of salts. This should indicate moisture in the system. If this condition exists, the receiver-dehydrator should be replaced and the system evacuated for one hour.

When leak-testing the POA valve, it is necessary to check only the hose coupling ends. When using a Propane Torch Leak Detector, no evidence of refrigerant should be present at the POA valve.

The POA valve will provide different gauge readings based on the altitude where the readings are being taken. Correct gauge reading at sea level is 29.5 psi. Gauge readings will be one-half psi higher for each additional 1000 feet of elevation.

The only test for POA valve operation is to check the suction pressure at the valve when making a performance test. If the valve gives improper gauge readings, it must be replaced since it is not repairable or adjustable.

EXPANSION VALVES

Internally Equalized Type

Referring to Fig. 18, the refrigerant enters the inlet and screen as a high pressure liquid. The refrigerant flow is restricted by a metered orifice through which it must pass. As the refrigerant passes through this metered orifice, it changes from a high pressure liquid to a low pressure liquid or from the high side to the low side.

The refrigerant flow through the metered orifice is of the utmost importance. Anything that interferes with this flow seriously affects operation of the entire system.

A sufficient drop in temperature of the area cooled by the evaporator changes the heat transfer requirement of the evaporator. To continue the same flow of

refrigerant into the evaporator will result in extreme cooling of the evaporator fins and coils to such an extent that they will freeze over with ice and stop air flow over them.

The flow of refrigerant is controlled by varying the amount of refrigerant allowed to pass through the metered orifice. This is accomplished by internal balancing pressures moving a valve or a seat to control the refrigerant flow.

A thermal bulb connected to a diaphragm by a small line and filled with refrigerant gas such as Freon is secured firmly by a clamp to the evaporator tail pipe. The thermal bulb is sensitive to tail pipe temperatures. If the tail pipe becomes warm, the gas inside the bulb will begin to expand, exerting pressure against the diaphragm on the top plate that is connected to the seat or valve by a pin or pins (whichever construction is used). This expansion will then move the seat away from the orifice, allowing an increased refrigerant flow. As the tail pipe temperature drops, the pressure in the thermal bulb also drops, allowing the valve to restrict flow as required by the evaporator.

The pressure of the refrigerant entering the evaporator is fed back to the underside of the diaphragm through the internal equalizing passage. Expansion of the gas in the thermal bulb must overcome the internal balancing pressure before the valve will open to increase refrigerant flow.

A spring is installed against the valve and adjusted to a pre-determined setting at the time of manufacture. This is the super-heat spring, the purpose of which is to prevent slugging of the evaporator with excessive liquid. The adjusted tension of this spring is the determining factor in the opening and closing of the expansion valve. During opening or closing, the super-heat spring tension will retard or assist valve operation as required.

NOTE: For all practical purposes we should not be concerned with the adjustment of this spring. Tension is adjusted from 4 to 16 pounds as required for the unit on which it is to be installed. This original setting is sufficient for the life of the valve, and tampering with the adjustment will only lead to an unsatisfactory operating unit. Special equipment is required in most cases to accurately calibrate this adjustment.

Externally Equalized Type

Operation of this type valve, Fig. 19, is the same as the internally equalized valve except that the evaporator pressure is fed against the underside of the diaphragm from the tail pipe of the evaporator by an equalizer line. This balances the temperature of the tail pipe through the expansion valve thermal bulb against evaporator pressure taken from the tail pipe.

Service Precautions

From the foregoing description of the thermostatic expansion valve, it can readily be seen that the valve is more sensitive to foreign materials than any other unit in the A/C system. Therefore, the following points should be observed to protect the valve while in service and while servicing the system.

1. The A/C system should be operated at least for short periods throughout the winter season to prevent the internal moving parts from corroding and sticking, which will result in the valve becoming inoperative and necessitating replacement. Periodic operation will also lubricate the entire system and especially the compressor seal, keeping it soft and in condition properly to seal the refrigerant.
2. Clean and replace all accessible screens when servicing.
3. Install a filter if system has excessive foreign materials present.
4. Follow correct evacuation procedure to remove all possible moisture from system.
5. Cap or cover any lines opened for service to prevent entrance of moisture or dirt.
6. Replace dehydrator as soon as excess moisture content is evident. Any system should have the dehydrator replaced at least upon opening the system the third time for service. Also, any time the system has been opened for a prolonged period from accident or rupture, replace the dehydrator.
7. Handle the thermal bulb and line with extreme care, as excessive bending and rough handling can cause a break that will release the gas, rendering the valve inoperative.
8. Use a back-up wrench when removing any connection to prevent twisting of a line, which may result in weakening or breaking it.
9. Replace expansion valve only with a comparable valve. A numbering system is used to designate the orifice size. Replacing the valve with one with either too small or too large an orifice can seriously affect system operation.
10. Maintain corrosion-free positive contact between thermal bulb and tail pipe. Over a period of time corrosion will form between the two contact surfaces and insulate the two surfaces to such an extent that the operation of the expansion valve will be affected. The clamp may also work loose, preventing positive contact between the two and again affect operation of the expansion valve.

Fig. 20 Path of magnetic flow through compressor clutch

COMPRESSOR CLUTCHES

The clutch units found on automotive A/C systems are of two general types. The first type developed had the magnetic coil installed inside the pulley and rotated with it. This type is called the rotating coil type. The electrical current is carried to the coil by the use of brushes mounted to the compressor frame and contacting a slip ring mounted to the inside of the rotating pulley.

The second type has the magnetic coil mounted to the frame of the compressor and does not rotate. This is called the stationary coil type. This coil being stationary, correct spacing becomes important to prevent the rotating pulley from contacting the coil and still bring the hub and armature into position to obtain the maximum attraction of the magnetic force.

Each clutch manufacturer furnishes units to fit all models of compressors according to the required specifications for 6 and 12 volt applications. Therefore, when replacing either the clutch unit or the coil, note carefully that the replacement unit is correct for the vehicle on which it is to be installed.

All clutches operate on the same principle of magnetic attraction. The operation is the same whether the magnetic coil is so mounted that it rotates with the pulley or is solidly mounted to the compressor. Each has a wound core located within a metal cup acting in a manner similar to a horseshoe magnet when the coil is energized magnetically, Fig. 20.

Testing Clutch Coil

To determine if a clutch coil is defective, the following general procedure is enough to meet all requirements regardless of variations of installation. Meter connections given are for negative ground systems; reverse connections for positive ground systems.

Determine Voltage to Coil

1. With ignition switch on and clutch energized, battery voltage should be delivered to the coil. To prepare for the test, expose the connection between the coil and evaporator for electrical checks. *Do not allow exposed wire to contact body of car while switches are ON.*

2. Connect RED lead of a conventional Volt-Ammeter Tester to the exposed wire connection between evaporator and clutch coil.
3. Connect BLACK lead of voltmeter to compressor body.
4. Voltmeter should register battery voltage. If there is no voltage indication, check line fuse, voltage into evaporator, and to the "OFF-ON" switch to locate and repair voltage loss.

Determine Current Draw of Coil

1. Seperate wires at connection between evaporator and coil.
2. Connect RED ammeter lead to exposed wire of evaporator.
3. Connect BLACK lead of ammeter to clutch coil wire.
4. Turn switches ON to energize clutch coil.
5. Ammeter should indicate 3 amperes for 12-volt systems; 5 amperes for 6-volt systems.
6. A zero ampere draw indicates an open circuit inside coil; excessive current draw indicates a short-circuit within the coil.

Determine Ground Circuit Resistance

Performance of the resistance test requires that the current draw of the coil be within specifications given above.

1. Connect evaporator and clutch coil wire.
2. Connect RED lead of voltmeter to compressor body.
3. Connect BLACK lead of voltmeter to battery post.
4. Turn switches ON to energize clutch coil.
5. Total resistance from compressor body to battery post cannot exceed .3 of a volt.
6. If resistance is excessive, clean all connections and metal-to-metal contacts, including engine-to-body and compressor-to-engine, to reduce resistance.
7. If the clutch coil is defective, replace it as outlined in the *Service Components* section of this chapter further on.

A/C System Testing

PERFORMANCE TEST

The system should be operated for at least 15 minutes to allow sufficient time for all parts to become completely stabilized. Determine if the system is fully charged by the use of test gauges and sight glass if one is installed on system. Head pressure will read from 180 psi to 220 psi or higher, depending upon ambient temperature and the type unit being tested. The sight glass should be free of bubbles if a glass is used in the system. Low side pressures should read approximately 15 psi to 30 psi, again depending on the ambient temperature and the unit being tested. It is not feasible to give a definite reading for all types of systems used, as the type control and component installation used on a particular system will directly influence the pressure readings on the high and low sides (see Fig. 5).

The high side pressure will definitely be affected by the ambient or outside air temperature. A system that is operating normally will indicate a high side gauge reading between 150-170 psi with an 80°F ambient temperature. The same system will register 210-230 psi with an ambient temperature of 100°F. No two systems will register exactly the same, which requires that allowance for variations in head pressures must be considered. Following are the most important normal readings likely to be encountered during the season.

Ambient Temp.	High Side Pressure
80	150-170
90	175-195
95	185-205
100	210-230
105	230-250
110	250-270

Relative Temperature of High and Low Sides

The high side of the system should be uniformly hot to the touch throughout. A difference in temperature will indicate a partial blockage of liquid or gas at this point.

The low side of the system should be uniformly cool to the touch with no excessive sweating of the suction line or low side service valve. Excessive sweating or frosting of the low side service valve usually indicates an expansion valve is allowing an excessive amount of refrigerant into the evaporator. This condition will not necessarily be applicable to those units installed on General Motors vehicles that use the Suction Throttling valve. On these systems the line from the valve to the compressor will normally drop to a much lower reading than the evaporator pressure as the Suction Throttling Valve closes, resulting in the presence of moisture or frosting on this line. This is a normal reaction in this type system and is the result of the construction and operation of the STV or POA and the compressor, having approximately 35% more capacity than previous models of these vehicles that used the hot gas by-pass valve. These factors often cause the line from the STV or POA to the compressor to drop into a partial vacuum under normal operation.

Evaporator Output

At this point, provided all other inspection tests have been performed, and components have been found to operate as they should, a rapid cooling down of the interior of the vehicle should result. The use of a thermometer is not necessary to determine evaporator output. Bringing all units to the correct operating specifications will insure that the evaporator performs as intended.

Fig. 23 Temperature-pressure relationship for F12 or R12 refrigerant

PURGING SYSTEM

1. Connect gauges into system, Figs. 21, 22, and adjust controls for maximum cooling. *This is necessary when the system has not been operating to return excess oil to the compressor.*
2. Operate engine for 10 to 15 minutes to stabilize the system at 1500-1750 rpm.
3. Shut off engine and controls. Adjust engine speed to slow idle to prevent "dieseling".
4. Open low side hand manifold valve slightly, using a rag or container to catch refrigerant. *Do not discharge the refrigerant near an open flame as a toxic gas (phosgene) can result.*
5. Open high side manifold hand valve. *Open hand valves only enough to bleed refrigerant from system. Too rapid purging will draw excessive oil from compressor and system.*
6. Close gauge manifold shut-off valves when refrigerant ceases to bleed from hose. Both gauges will read zero psi.

Evacuate System with Vacuum Pump

Vacuum pumps suitable for removing air and moisture from A/C systems are commercially available. A specification for system pump-down used here is 28 to 29½" vacuum. This reading can be attained at or near sea level only. For each 1000 feet of altitude this operation is being performed, the reading will be 1" vacuum higher. As an example, at 5000 feet elevation, only 23-24½" of vacuum can be obtained.

1. Connect vacuum pump to gauge manifold. With gauges connected into system, remove cap from vacuum hose connector. Install center hose from gauge manifold to vacuum pump connector. Mid-position high and low side compressor service valves (if used). Open high and low side gauge manifold hand valves.
2. Operate vacuum pump a minimum of 30 minutes for air and moisture removal. Watch compound gauge that system pumps down into a vacuum. System will reach 28-29½" vacuum in not over 5 minutes. If system does not pump down, check all connections and leak-test if necessary.
3. Close gauge manifold hand valves and shut off vacuum pump.
4. Check ability of system to hold vacuum. Watch compound gauge to see that gauge does not rise at a faster rate than 1" vacuum every 4 or 5 minutes. If compound gauge rises at too rapid a rate, install partial charge and leak-test. Then purge system as outlined above.
5. If system holds vacuum, charge system with refrigerant.

Evacuate System Using Charging Station

A vacuum pump is built into the charging station and is constructed to withstand repeated and prolonged use without damage. Complete moisture removal from the system is possible only with a vacuum pump constructed for the purpose.

1. Operate vacuum pump. Connect hose to vacuum pump if system was purged through charging station.
2. Open high and low side gauge valves of charging station.
3. Connect station into 110-volt current.
4. Engage "Off-On" switch to vacuum pump according to directions of specific station being used.
5. System should pump down into a 28-29½" vacuum in not more than 5 minutes. If system fails to meet this specification, repair as necessary.
6. Operate pump a minimum of 30 minutes to remove all air and moisture.
7. Close high and low side gauge valves. Open switch to turn off pump.
8. Check ability of system to hold vacuum by watching compound gauge to see that it does not rise at a rate higher than 1" of vacuum every 4 or 5 minutes: If rise rate is not within specifications, repair system as necessary. If rise rate is

within specifications, charge system with refrigerant.

Evacuate System Using Car Engine as a Pump

This procedure is recommended to be used only in an emergency. If a vacuum pump is not available, the compressor should be operated no longer than necessary to remove air from the system. *A vacuum pump must be used for complete moisture removal. The practice of using the car's engine to operate the compressor as a vacuum pump will prove detrimental to the compressor. No compressor manufacturer recommends this procedure.*

1. With gauges connected into system, mid-position high and low side compressor service valves (if used). Open high side gauge manifold hand valve. Operate engine at slow idle speed.
2. Close high side gauge manifold hand valve when compound gauge reaches 20-25" of vacuum.

NOTE: When using the car engine for pump-down, the compound gauge will seldom if ever drop after 25" of vacuum. Continued operation after 25" of vacuum has been reached will increase wear and cause possible damage to the compressor as it is operating without sufficient lubrication.

3. Shut off car engine. Then check ability of system to hold a vacuum by watching the compound gauge to see that gauge does not rise at a faster rate than 1" vacuum every 4 or 5 minutes. If compound gauge rises at too rapid a rate, install a partial charge and leak-test the system. Then purge system and repeat above procedure. If gauge rise is satisfactory, charge system with refrigerant.

CHARGING THE SYSTEM

Using 15-Ounce Containers

To prevent waste and to aid in more accurate charging, refrigerant manufacturers package refrigerant in 15-ounce cans. The small containers are advantageous to small shops doing only a limited amount of A/C service work. The small containers are handled in the same manner as the larger drums except care must be taken not to overheat the cans because of the danger of explosion.

1. Install "Fitz-All" valve to container(s). The Fitz-All valve is available for single cans or three cans. Whichever is used, preliminary installation to the can(s) is the same.
2. Close shut-off valve of Fitz-All valve. Pierce can with mechanism which is part of Fitz-All valve.
3. With the system pumped-down, install charging hose to Fitz-All valve. Loosen charging hose at center connector on gauge manifold.
4. Crack Fitz-All shut-off valve to purge air from charging hose. Tighten charging hose connection on gauge manifold and close shut-off valve.
5. Partially charge system by opening high side gauge manifold hand valve. Open shut-off valve on Fitz-All valve. Invert container(s) to allow liquid Freon to enter high side of system.
6. Complete charge of system. Do not overfill. Use A/C Data table to determine capacity of system being serviced. Close high side gauge manifold hand valve. Start engine and adjust throttle to 1500-1750 rpm. Adjust A/C controls for maximum cooling. Open low side gauge manifold hand valve to allow Freon to be drawn into system. If single containers are used, it will be necessary to replace each as it becomes empty. Watch sight glass until bubbles disappear.
7. To check charge in system, watch for bubbles in sight glass (if used). Read high pressure gauge indication. *Excessive head pressure with a normal low side pressure indicates an overcharge of Freon or air in system. Compressor may or may not be noisy.*
8. Listen for hissing noise in expansion valve as many systems have a hissing in the expansion valve until the system is fully charged.
9. Continue testing system and adjust controls for maximum efficiency.

Using Charging Station

Most stations contain a charging cylinder into which the exact amount of refrigerant required for the system being serviced may be placed while system pump-down is being performed. The refrigerant charging cylinder contained in the station is heated to the correct temperature to insure proper refrigerant flow to all parts of the system as a gas during the charging operation, Fig. 21. Following correct evacuation procedure as to length of time for complete moisture removal, the vacuum pump will so efficiently pump-down the system that opening the correct valves will completely charge the system from the high side, and the use of the compressor in the charging operation will not be required.

1. Prepare charging cylinder for filling: Open storage drum valve. Close all valves on station. Read storage tank gauge pressure. Rotate dial shroud on charging cylinder to correlate with pressure on gauge. Open cylinder fill valve.
2. Fill charging cylinder: Determine system capacity from A/C Data table. Intermittently open and close pressure relief valve. *When pressure relief valve opens, Freon will enter cylinder and boil. Closing the valve will increase pressure on the Freon, changing it to a liquid to stabilize the refrigerant in the sight glass. Fill to specified level in sight glass and close pressure relief valve.*
3. Charge system: With gauges connected into system, open refrigerant control valve. Open high pressure valve. Remove vacuum hose from pump and crack (barely open) low pressure valve. Allow refrigerant to escape through vacuum hose for approximately 3 seconds. Close high and low pressure valves, and close refrigerant control valve.
4. Continue testing system and adjust controls for maximum efficiency.

LEAK TEST SYSTEM

The propane torch Halide Leak Detector is the most widely used of the detection devices. Therefore, only the procedure for this device will be given. The procedure is the same for any electronic detector, except that the pick-up device registers the presence of refrigerant by a flashing light or high pitched squeal instead of changing the color of the flame. All other steps in preparing the system and leak testing are the same and can be followed as outlined below.

1. Stabilize system at 1500-1750 rpm. If system is empty of refrigerant, it will be necessary to install a partial charge before continuing. With gauges connected into system, adjust A/C controls for maximum cooling. Operate for 10 to 15 minutes, then shut off car engine.
2. Light leak detector. Open valve to a low flame that will not blow itself out. Warm up until copper element turns cherry red. Lower flame until flame tip is even or slightly below center of element. *(For electronic tester, follow preparation procedure as given in operating instructions.)*
3. Move leak detector pick-up under hoses, joints, seals, and any possible place for a leak to occur.

NOTE: Freon 12 refrigerant is heavier than air and will move downward. If concentration of refrigerant is located, move pick-up upward to locate leak. Do not inhale fumes produced by burning refrigerant.

4. Watch for color change of flame: Pale blue, no refrigerant; yellow, small amount of refrigerant; purplish-blue, large amount of refrigerant. Repair system as necessary if leaks are located.
5. Check sensitivity of reaction plate: Pass pick-up hose over empty can or crack open refrigerant container; flame should show violent reaction. If no color change, replace reaction plate, following instructions accompanying leak detector. *Too high a flame will result in short life to reaction plate and poor reaction and will soon burn out element.*
6. Charge system if repairs were necessary.

ISOLATE COMPRESSOR FROM SYSTEM

On systems having both a high side and low side service valve, the compressor may be isolated and refrigerant retained in the system while service work is being performed on the compressor or in the engine compartment of the car.

1. Stabilize system at 1500-1750 rpm: With gauges connected into system, adjust A/C controls for maximum cooling. Operate system for 10 to 15 minutes.
2. Isolate compressor: Slowly close low side service valve until low side

gauge reads zero psi. Then shut off car engine.

3. Return car engine to idle speed to prevent "dieseling". Completely close low side service valve. Close high side service valve. Purge refrigerant from compressor by cracking low side hand manifold until both gauges read zero psi. *Purge refrigerant slowly to prevent pulling oil from compressor.*
4. Remove gauges from service valves and service valves from compressor. Then perform service work as required.
5. Place compressor in system: Install service valves to compressor, using new gaskets or O-ring seals, whichever are required. Purge air from compressor by cracking high side service valve for 3 seconds with high side hose connector capped and low side hose connector open.
6. Install gauges to service valve connectors and purge air from hoses.
7. Mid-position service valves, continue testing system and adjust controls for maximum performance.

Each make and model of A/C system has its own type of construction. To cover service work on each component of all models is beyond the scope of this manual. An effort is made to cover the difficulties of most frequently encountered service procedures. Service work to be performed on components not found in the following pages will offer little difficulty.

Servicing System Components

COMPRESSOR CLUTCH, REPLACE

Air-Temp, Tecumseh & York

After determining that the clutch coil is defective as checked elsewhere in this chapter, replace the coil as outlined below, referring to Figs. 24, 25, 26.

Remove Compressor Pulley

1. Remove bolt from compressor shaft.
2. Remove compressor drive belt.
3. Thread 2½" bolt into hub center.
4. Tighten bolt against compressor shaft and lift off pulley when loosened. *If hub center is not threaded, reinstall lock bolt about ½ its length into compressor shaft. Grasp pulley firmly and sharply strike end of bolt to loosen pulley.*

Inspect Rotating Type Coil

1. Inspect slip ring(s) for evidence of scoring, arcing and general condition.
2. Use continuity tester to check coil winding for open circuit.
3. Replace coil and pulley assembly if defective.
4. Inspect condition of brush(s).
5. Replace brush assembly on compressor housing if defective.

Stationary Type Coil

1. Disconnect coil lead(s).
2. Remove coil retainer screws from seal plate and remove coil from compressor.
3. Install new coil into seal plate and tighten bolts finger tight.
4. Install plastic aligner ring (if used) on coil.
5. Alternately tighten coil retainer bolts gradually and evenly until all are tightened securely.
6. Connect coil wire(s).

Install Pulley

1. Align keyway in hub with key in shaft and press on pulley.
2. Install retainer bolt. Install and adjust drive belt.
3. Momentarily engage clutch coil and tighten lock nut securely.

FRIGIDAIRE CLUTCH, REPLACE

Removal, Figs. 27, 28

1. Remove clutch plate and hub assembly.

Fig. 24 Warner clutch used on Air-Temp compressors

Fig. 25 Pitts Electro-Loc clutch used on Air-Temp compressors

Fig. 26 Eaton clutch used on on Tecumseh and York compressors

2. Remove pulley and bearing, Figs. 29, 30, 31.
3. Note position of terminals on coil housing and scribe location on compressor front head casting.
4. Remove coil housing retainer ring, Fig. 32.

Installation

1. Position coil and housing assembly on compressor front head casting so electrical terminals line up with marks previously scribed on compressor.
2. Align locating extrusions on coil housing with holes in front head casting.
3. Install coil housing retainer ring with flat side of ring facing coil.
4. Install pulley and bearing assembly.
5. Install clutch plate and hub.

COMPRESSOR SEAL, REPLACE

Air-Temp, Tecumseh & York

Removal

1. If system has not lost refrigerant charge, follow procedure on isolating the compressor as outlined previously.
2. If system does not have service valves, purge refrigerant from system, or if system is empty of refrigerant disregard above steps.
3. Referring to Figs. 33 to 35, remove seal plate by lifting out key from shaft and remove screws holding seal plate to compressor. Pry off seal plate by applying pressure against tangs on each side of plate. Discard plate.
4. Use small screwdriver to pry seal from housing. *Do not scratch shaft as leak will result.* Discard old seal parts.

Installation

1. Clean and lubricate all parts before reassembly. Clean old gasket from housing. Wipe compressor shaft and housing with clean dry cloth. Flush all surfaces with refrigerant oil to remove lint and dust.
2. Lubricate new seal with refrigerant oil and install seal onto shaft. *Do not touch carbon face with fingers.*
3. Align seal over pins on installations requiring pin alignment.
4. Flush carbon face with refrigerant oil.
5. Install new seal plate (comes with seal kit as two surfaces have been seated to each other).
6. Lubricate seal plate gasket with refrigerant oil and locate on compressor housing.
7. Install two guide studs on installations that require compression of

Fig. 27 Exploded view of Frigidaire compressor

seal during assembly.

8. Lubricate seal plate surface, install on compressor housing and install bolts finger tight.

NOTE: To prevent the possibility of seal leakage due to uneven tightening, install all screws and finger tighten them alternately from side to side gradually and evenly until all are tight. Final tightening should be done in the same manner and torque, to 9-12 ft-lbs. Then remove three screws that hold clutch coil, install coil and retighten to 9-12 ft-lbs.

9. Install pulley onto compressor shaft.
10. Purge air from compressor or evacuate system for moisture removal.
11. Charge system with refrigerant.
12. Adjust controls for maximum performance.

Fig. 28 Sectional view of Frigidaire compressor

Fig. 33 Chrysler Air-Temp compressor. From 1962

Fig. 29 Removing pulley bearing retaining ring

Frigidaire, 1963-68

Removal

1. Remove clutch plate and hub.
2. Remove seal seat retainer ring, Fig. 36. *Illustration shows coil and housing removed, but this is not necessary.*
3. Remove seal seat, Fig. 37. Grasp seal seat with tool flanges and pull straight up on end of tool to remove seal seat.
4. Remove shaft seal assembly, Fig. 38. Press down on tool to overcome seal spring pressure and twist tool clockwise to engage tabs on seal with locking tangs on tool. Remove seal by pulling straight out from shaft.
5. Remove O-ring seal from interior of front head casting bore. A wire with

Fig. 31 Installing bearing in pulley

Fig. 30 Removing bearing from pulley

Fig. 32 Removing coil housing retaining ring

Fig. 34 Tecumseh compressor shaft seal

Fig. 35 York compressor shaft seal

Fig. 36 Removing seal seat retaining ring. Frigidaire from 1962

Fig. 37 Removing seal seat. Frigidaire from 1962

a hook formed on its end may be used, Fig. 39.

Installation

1. Check front head casting bore for carbon chips of old seal or other foreign material. Clean bore thoroughly before installing new seal.
2. Install new O-ring seal in groove in front of head casting bore, making certain that O-ring seal is installed in bottom groove, Fig. 40. Top groove is for retainer ring.
3. Immerse shaft seal in clean refrigerant oil before installing to prevent shoulder from damaging O-ring seal.
4. Insert shaft seal over flats on shaft with carbon seal up, Fig. 38. Turn tool counterclockwise to release it from seal tabs and remove tool.
5. Insert seal seat into front head casting bore until it contacts shaft seal, being careful not to dislodge O-ring in bore. *Contact surface of seal must be protected against any damage, such as scratches and nicks. Even finger marks may cause surface damage.*
6. Insert seal seat retainer ring until retainer rests on seal seat, Fig. 36.
7. Remove snap ring pliers and, using tool shown in Fig. 37, press down on retainer ring until spring pressure of shaft seal is overcome and retainer ring snaps into its groove in casting bore, Fig. 40. Chamfer that can be seen from shaft end is a land, not a groove.
8. Install clutch plate and hub.
9. Perform compressor leak test.

Fig. 39 Removing shaft seal O-ring. Frigidaire from 1962

Fig. 38 Removing shaft seal. Frigidaire from 1962
